ABSTRACT

A novel density functional method is presented for the calculation of electronic and thermodynamical properties of oligosaccharides. This method, termed K2-BVWN, offers two advantages; it scales as  $N^3$ , where  $N$  is the number of basis functions, and there are only two adjustable parameters. The current density functional method is tested in terms of reproducing high level gas phase *ab initio* calculations in eleven low energy conformers of D-glucopyranose including exo-anomeric and different hydroxymethyl orientations ( $G^-$ ,  $G^+$ , and  $T$ ). The K2-BVWN method is also tested in terms of reproducing the spectroscopic features of D-glucopyranose and D-mannopyranose ( $\alpha/\beta$ ) as compared with both a vibrational self-consistent field calculation (VSCF) as well as experimental infrared spectroscopy. The VSCF calculations offer the advantage that it is possible to include higher order mode coupling and anharmonic effects directly into the calculation of the vibrational frequencies. In general, the K2-BVWN method reproduces the *ab initio* energetic trends of the different conformers of D-glucose. While the absolute energies are not the same between the *ab initio* and the K2-BVWN method, both methods do predict a preference for the  $\alpha$ -anomer in the gas phase (0.4 kcal/mol *ab initio*, 0.0 – 0.5 kcal/mol K2-BVWN). The K2-BVWN method was able to reproduce the experimental and VSCF calculated spectrum of both D-glucopyranose and D-mannopyranose in the frequency range between 1500 – 800  $\text{cm}^{-1}$ . Because the current density functional method is both relatively quick and accurate, it represents a significant advancement in the development of oligosaccharide force fields.

## INTRODUCTION

Carbohydrates play a critical role in many biological processes from energy metabolism, glycolipid recognition, glycoprotein interaction to structural polysaccharides. They are the most ubiquitous of all biological molecules and yet some of the least understood. Even monosaccharides pose quite a theoretical challenge in terms of understanding the enormous conformational potential energy surface. This is due in part to the many torsional degrees of freedom, that is the rotation of the exocyclic hydroxyl and hydroxymethyl groups. Furthermore, at the anomeric carbon ( $C_1$ ) the hydroxyl group can take an equatorial or axial orientation. This leads to an anomeric equilibrium which can be determined experimentally by  $^{13}\text{C}$ NMR spectroscopy<sup>1-4</sup> and by optical rotation.<sup>5,6</sup> The problem of studying all of conformational space is further complicated when aqueous effects are included into the calculation. It is known for example that the anomeric equilibrium between  $\beta$ - and  $\alpha$ -D-glucopyranose favors the  $\beta$  anomer by 0.3 kcal/mol,<sup>7</sup> while in the gas phase, the anomeric effect is reversed to favor  $\alpha$ -D-glucopyranose by 0.4 kcal/mol.<sup>8,9</sup> Ideally, one may be interested in examining the relative energies of the anomers as well as the intramolecular rotational relationship of the hydroxyl and hydroxymethyl groups for D-glucopyranose and each of its epimers. Recently, Barrows and co-workers have investigated the hydroxyl/hydroxymethyl rotational and anomeric conformers of D-glucopyranose in the gas phase as well as in solution.<sup>9</sup> In this study, the authors used the MM3(96) program and found 107 unique low energy  $^4C_1$  conformers of  $\alpha$ -glucopyranose and 113 conformers of the corresponding  $\beta$ -glucopyranose by an exhaustive minimization procedure. From the MM3 calculations, eleven lowest energy structures were further studied by high level *ab initio* methods to deduce the relative energies between the conformers.<sup>9</sup> In a related study, Damm et al. also studied conformers of D-glucopyranose using both *ab initio* and density functional methods.<sup>10</sup> These studies are to date the most comprehensive *ab initio* investigations of glucopyranose.

A full quantum mechanical *ab initio* calculation is one of the most reliable theoretical methods in the study of atomic and molecular electronic and thermodynamical properties. In terms of the application of *ab initio* methods to the study of carbohydrates and carbohydrate model compounds, there is an ever increasing body of literature.<sup>8,9,11-20</sup> In fact *ab initio* calculations have been essential in the development of a variety of molec-

ular mechanical carbohydrate force fields.<sup>10,21-26</sup> While *ab initio* methods are extremely accurate, the price in computational cost make such methodology, to date, prohibitively expensive for all but mono and perhaps disaccharides. This is due primarily to scaling difficulties in *ab initio* methods. It is noted that methods such as Hartree Fock (HF) and MP2 offer reasonable scaling properties ( $N^3$  and  $N^5$  respectively); however, higher correlated and hence higher accuracy treatments (QCI and CC) scale roughly at  $N^7$ . A promising alternative to *ab initio* methods, with less stringent scaling properties, are density functional based (DFT) methods.<sup>27-31</sup> Recently, density functional methods have also been employed in the study of carbohydrates.<sup>11,12,16,17,19</sup>

The success of DFT methods in predicting electronic properties relies on the choice of the exchange-correlation energy functional used in the computation. A major advance of DFT methods came in the late 80's with the development of the hybrid-exchange functionals of Becke and the formulation of the generalized gradient approximations.<sup>32</sup> Today, one of the most popular semi-empirical DFT methods for predicting structures, energies and thermochemical properties is Becke's three-parameter procedure, B3LYP.<sup>32,33</sup> Becke introduced this hybrid HF-DFT method in which the exact nonlocal HF exchange is semi-empirically mixed with the local Slater exchange through the adiabatic connection formula.<sup>33</sup> The accuracy of such methods for predicting atomization energies is within 3 to 5 kcal/mol, however the scaling of such methods is still rather large ( $\sim N^4$  to  $\sim N^5$ ).<sup>27-31</sup> Recently Kafafi and co-workers have developed a semi-empirical HF-DFT based method which mixes the HF and gradient corrected local spin density exchange using the adiabatic connection formula<sup>33</sup> together with the Pade approximated Vosko, Wilk, and Nusair (VWN) correlation functional.<sup>34</sup> This method (K2-BVWN) offers two very attractive new features to DFT based methods; the scaling has been improved to  $\sim N^3$ ,<sup>35,36</sup> and there are only two adjustable parameters.<sup>36</sup> Using this method, Kafafi and co-workers were able to reproduce (within  $\pm 2$  kcal/mol) the heats of formation for over 300 molecular systems as well as the binding energies of noble gas dimers and hydrogen bonded complexes.<sup>35,36</sup> It is also noted that current developments in DFT approaches with linear scaling is an active area of research.<sup>31</sup>

The aim of the present work is to apply this novel density functional method to the calculation of the energetics and spectroscopy for  $\alpha, \beta$ -D-glucopyranoses and  $\alpha, \beta$ -D-

mannopyranose. In the study of D-glucopyranose, we investigated the relative energies of 11 different gas phase conformers as in the work of Barrows et al.<sup>9</sup> The resulting energy optimized spectrum for two of the conformers will be compared to both previous experimental spectroscopy<sup>37-39</sup> as well as vibrational frequencies obtained from a vibrational self consistent study (VSCF). Previously, Gregurick and co-workers refined parameters for an Amber-based carbohydrate force field utilizing the VSCF method and the experimental spectrum of  $\alpha$ -D-glucopyranose.<sup>40</sup> The VSCF method is quite unique in that anharmonic as well as mode coupling terms are included directly in the calculation of the vibrational frequencies. Using this spectroscopically refined force field, the authors then calculated the anomeric free energy difference between  $\alpha$  and  $\beta$  glycopyranose in solution. Based on six molecular dynamics simulations they found an average  $G_{\alpha \rightarrow \beta}^- \sim -0.1$  kcal/mol. However, the  $\Delta G$  ranged from 0.23 to  $-0.34$  kcal/mol. Moreover, while this force field reproduced the spectroscopic features of D-mannopyranose it could not reproduce the experimental free energy difference. The authors attributed this large variation in  $\Delta G$  values to be due in part to a difficulty in physically capturing the intermolecular hydrogen bonding between pyranose sugars and the surrounding solvent. It is therefore the future goal of the authors to develop and further improve oligosaccharide force fields by combining theoretical efforts in both DFT and VSCF based approaches.

## METHODS

### A. K2-BVWN Density Functional Method

All of the density functional theory (DFT) computations reported in this work were done using the K2-BVWN methodology of Kafafi and coworkers.<sup>35,36</sup> In the K2-BVWN scheme, the total exchange-correlation energy functional, Exc, was approximated by a sum of two terms. Namely, an exchange component, Ex, and a correlation term, Ec. The Ex term consisted of a hybrid mixture of 37.5% exact exchange and the appropriate local spin density exchange using the adiabatic connection formula.<sup>35</sup> On the other hand, the Ec component was a linear combination of the Vosko, Wilk and Nusair (VWN) correlation energy functional of the free electron gas, Ec(VWN),<sup>34</sup> and a generalized gradient approximation (GGA) term containing one adjustable parameter, as described in detail elsewhere.<sup>35,36</sup>

The K2BVWN method has previously been applied to the calculation of room temperature heats of formation, ionization potentials, electron and proton affinities of 350

molecular systems, including the G2 database of Curtiss et al.<sup>41</sup> The overall performance of the K2-BVWN methodology was comparable to the accurate G2 *ab initio* theory,<sup>41</sup> with a total average error in computed electronic and thermodynamic properties of 1.4 kcal/mol.<sup>35,36</sup> The main advantage of the K2-BVWN methodology over G2-theory is in its  $N^3$  scaling, where  $N$  is the number of basis functions, compared to  $N^7$  for G2-theory. Therefore, the K2-BVWN approach may be applicable to larger chemical systems than corresponding *ab initio* methods. The K2-BVWN methodology has been implemented into the Gaussian 94 computer code by Kafafi and coworkers.<sup>35,36,42</sup>

It is well known that the majority of reported DFT-based methods have a common difficulty in handling Van der Waals and charge-transfer interactions.<sup>28,30,27,35</sup> In general, DFT approaches normally underestimate the binding energies of these systems. In particular, Van der Waals complexes, such as dimers of noble gases, were predicted by various DFT methods to have either no, or strongly repulsive interactions. The K2-BVWN scheme has been shown to approximately overcome this difficulty that is inherent to other DFT methods.<sup>35</sup> The K2-BVWN method predicted the binding energies of 9 noble gas dimers (helium through Xenon) and a variety of charge-transfer complexes with remarkable accuracy.<sup>35</sup> This was shown to be due to the long-range behavior of the correlation potential,  $V_c$ , used in the formulation of this method. That is,  $V_c$  had a  $\sim \frac{1}{r^6}$  dependence as  $r \rightarrow \infty$ , which mimics the Van der Waals interactions. Therefore, the K2-BVWN methodology accounts for both electrostatic and Van der Waals non-bonded interactions reasonably well.

For all of the molecules investigated in this work, full geometry optimizations with analytical gradients using K2-BVWN/6-311g(d) level of theory were performed. These were followed by a single point computation using the K2-BVWN/6-311+g(3df,p) method. Geometry optimizations were generally terminated when the largest component of the gradient was smaller than 0.0001 Hartree/Bohr. Vibrational frequencies of all of the species of interest and corresponding thermal corrections were also computed using the K2-BVWN/6-311g(d) method. All of the optimization, diagonalization, numerical integration routines, and DFT exchange-correlation functionals used in connection with the K2-BVWN methodology were obtained from the Gaussian 94 computer code.<sup>35,36,43</sup>

## B. VSCF Method

In the Vibrational Self-Consistent Field (VSCF) calculations, we utilize an all atom force field as implemented in the molecular dynamics program MOIL.<sup>44</sup> A complete de-

scription of this force field may be found in the work of Gregurick et al.<sup>40</sup> The parameters which describe the dihedral torsional barriers and atomic partial charges were determined by fitting our VSCF vibrational frequencies to the experimental IR and Raman frequencies ( $\alpha$ -D-glucopyranose only) of Dauchez and co-workers,<sup>45</sup> Korolevich and co-workers,<sup>37,38</sup> and Atalla and Wells.<sup>39</sup> This reparameterized force field yielded excellent agreement not only in reproducing the vibrational spectrum of both  $\alpha$  and  $\beta$ -glucopyranose (errors are  $\pm 3.3 \text{ cm}^{-1}$  for  $\alpha$ -glucopyranose, and  $\pm 5.1 \text{ cm}^{-1}$  for  $\beta$ -glucopyranose) but also reproduced a reasonable estimate of the anomeric free energy difference (D-glucopyranose only) between these two anomers in solution.<sup>40</sup>

In the VSCF method, the  $N$ -dimensional Schrödinger equation is solved by making the approximation that the wavefunction representing each normal mode is near separable. Furthermore the normal quadratic equilibrium expansion of the potential (harmonic case) is extended to fourth order. This expansion is valid about a single minimum. In principle, the spectroscopy depends on the specific conformer, and a previous study of the peptide di-L-serine illustrated that different minima had different spectroscopic frequencies.<sup>46</sup> Thus for a complete spectroscopic study of all conformations, a separate expansion for each unique conformer will be required.

In the VSCF method, each degree of freedom, or normal mode, is solved separately for by integrating over all the other degrees of freedom. This then leads to  $N$  single mode VSCF equations. In the present calculation we solved each VSCF Hamiltonian using the collocation method of Yang and Peet.<sup>47</sup> For an adjustable grid, sensitive to each mode, we choose to work in the dimensionless variable,  $\bar{q}_k$ , where

$$\bar{q}_k = \frac{Q_k}{(\lambda_k)^{\frac{1}{4}}}.$$

Here,  $\lambda_k$  is the  $k^{\text{th}}$  eigenvalue of the Hessian. Convergence was determined when  $\Delta \sum_k \epsilon_k \leq 0.0001 \text{ kcal/mol}$  from one iteration to the next. The calculations were carried out on a Silicon Graphics Indigo workstation. A complete description of the VSCF methodology and application may be found in references 40, 46, and 48-50.

## RESULTS AND DISCUSSION

### A. Structures and Energetics

In the present work, we compare the eleven lowest energy conformers of both  $\alpha$ -

and  $\beta$ -D-glucopyranose as in the work of Barrows et al. (Figure 1).<sup>9</sup> In our present DFT method, a full optimization with analytic gradients was performed at the K2-BVWN/6-311g(d) level of theory. These were then followed by a single point calculation at the K2-BVWN/6-311+g(3df,p) level. Table 1 summarizes the calculated relative energies in kcal/mol for the conformers of D-glucopyranose in the gas phase. Using a high level of theory (MP2/cc-pVDZ) Barrows and co-workers were able to illustrate that in the gas phase the  $\alpha$  anomer is stabilized over the  $\beta$  by 0.4 to 0.6 kcal/mol.<sup>9</sup> In the present calculations we find that the conformer number 7 ( $G^+$ ) is the lowest energy structure, which is not in complete agreement with the *ab initio* results. From table I, the lowest *ab initio* energy conformer is the  $G^-$  conformer number 8. However, we do find that the  $G^+$  and  $G^-$  conformers are lower in energy than the T conformers as in the *ab initio* calculations.

In the study of the effect of the hydroxyl orientation, two conformers had a completely clockwise orientation of intramolecular hydrogen bonding (numbers 1 and 10). Conformer number 1 represents the clockwise  $\beta$  anomer while conformer number 10 is the clockwise  $\alpha$  anomer. In this case, the  $\alpha$  anomer is stabilized over the  $\beta$  by 1.98 kcal/mol. Although the absolute energies are different between the *ab initio* and K2-BVWN calculation, the stabilization of the  $\alpha$  anomer over  $\beta$  is the same for both calculations. This stabilization may be due to a better intramolecular hydrogen bond between the hydroxyls at positions  $C_1$  and  $C_2$  for the  $\alpha$  anomer. As in the *ab initio* calculations, we also find evidence for the  $C_1$  hydroxyl orientation to take advantage of the exo-anomeric effect. In this case, the clockwise conformers number 2 ( $\beta$ ) and 11 ( $\alpha$ ) have an energy difference of roughly 0.5 kcal/mol in favor of the  $\alpha$  conformer. In general the energy difference between the  $\alpha/\beta$  pairs in the present calculation is roughly  $\sim 0.8$  kcal/mol, which is only slightly less than for the *ab initio* calculations (1 kcal/mol). An estimation of the K2-BVWN free energy difference between  $\alpha$  and  $\beta$ , using the rovibrational contribution to the free energy from the work of Barrows and co-workers yields an estimate of  $\Delta G_{\alpha \rightarrow \beta}$  of  $\sim 0.0$  to 0.5 kcal/mol. The *ab initio* calculated free energy difference of the  $\alpha \rightarrow \beta$  anomerization was 0.4 kcal/mol in the gas phase.

### B. Calculation of Spectroscopic Frequencies and a Comparison with VSCF Frequencies and Experimental Frequencies

One of the main aims of the present study is to present a methodology which can not only accurately predict energetics of carbohydrate compounds but also predict vibra-

**Figure 1.** The eleven conformers of D-glucopyranose calculated at the K2-BVWN/6-311g(d) level. These are the same conformations as in the original work of Barrows et al.<sup>9</sup>

tional frequencies as well as thermodynamic properties. In this section, we illustrate that the present density functional method (K2-BVWN) will reproduce the vibrational spectrum of not only D-glucopyranose but also D-mannopyranose. We have selected two conformers of D-glucopyranose, conformer number one and ten (Figure 1) to represent  $\beta$ - and  $\alpha$ -D-glucopyranose, respectively. These conformers were selected based on the previous work of Gregurick et al.<sup>40</sup> However, they are not the lowest K2-BVWN energy structures and in any complete discussion of the spectroscopy, all of lowest energy conformers should be

b. Reproduced from Table 1 of Barrows et al.<sup>9</sup>

**Figure 2.** The conformers of  $\alpha$  (upper) and  $\beta$ -D-mannopyranose (lower) calculated at the K2-BVWN/6-311 g(d) level.

included. These conformers were chosen so as to make a comparison with the VSCF calculations more meaningful. The  $\alpha$ - and  $\beta$ - conformers of D-mannopyranose were generated from the corresponding  $\alpha$  and  $\beta$  conformers of D-glucopyranose by switching the H and OH groups at the  $C_2$  position and then optimizing at the K2-BVWN/6-311 g(d) level. The two anomers of D-mannopyranose are illustrated in Figure 2.

We have calculated the K2-BVWN vibrational frequencies and IR intensities for the anomers of D-glucopyranose and D-mannopyranose by a diagonalization of the energy optimized Hessian. We have also calculated the VSCF frequencies. The frequencies obtained from this method will include both anharmonic and mode coupling effects which are not

yet possible to capture directly from the density functional method. In the future we would like to refine the existing molecular mechanics force field, which the VSCF calculations are based on, using this density functional method. Thus an underlying comparison between the two methods, as well as the experimental spectrum, is imperative. For the comparison of the results for D-glucopyranose we choose the room temperature experimental infrared spectrum of Korolevich and co-workers in part because these authors have made an accompanying valence force field calculation of the frequencies.<sup>37,38</sup> For the D-mannopyranose spectrum, we used the crystalline IR frequencies (100 K) of Wells and Atalla.<sup>39</sup> Tables 2 and 3 list a comparison of the vibrational spectrum for D-glucopyranose ( $\alpha$  and  $\beta$ ) while Tables 4 and 5 is a comparison of the vibrational spectrum for D-mannopyranose ( $\alpha$  and  $\beta$ ). Table 6 list the average errors in the calculated frequencies for both  $\alpha/\beta$  glucopyranose and  $\alpha/\beta$  mannopyranose. In calculating the averages we did not include the (*OH*)<sub>s</sub> frequencies, as these are overestimated in the K2-BVWN method due to an unavoidable shortening of the OH bond. In this case, the OH stretching frequencies should be rescaled by  $\sim 8\%$  in order to compare well with the experimental and VSCF frequencies.

In general both the K2-BVWN and VSCF methods compare well in terms of reproducing the vibrational spectrum for mannopyranose and glucopyranose in the region between 1500 and 900  $\text{cm}^{-1}$ . However, both methods have difficulty in reproducing the lower frequency vibrations ( $< 800 \text{ cm}^{-1}$ ), particularly for  $\alpha/\beta$  mannopyranose. In the case of the mannopyranose spectrum the comparison between the experimental and calculated frequencies became extremely difficult below 500  $\text{cm}^{-1}$ , and in general, the assignment to the experimental frequencies in this region is suggestive at best.

In all four spectra, we calculate two bands at roughly 1530 and 1500  $\text{cm}^{-1}$  which have no corresponding experimental frequency. Previously Gregurick, et al.<sup>40</sup> speculated that the change in the dipole moment associated with these two modes may be rather small, which may explain why they do not show up in the experimental or Valence Force Field spectrum.<sup>40</sup> Based on an eigenvector analysis, these modes were assigned to a COH distortion and to a distortion of the ring. In general the COH and CCH distortion modes occur in the region from 1490 to 1300  $\text{cm}^{-1}$ . It was previously illustrated that the COH distortion will strongly couple to the methylene and methine modes,<sup>45,40</sup> which will shift the VSCF frequencies to the blue relative to the K2-BVWN frequencies. In this region of the spectrum, the VSCF frequencies agree slightly better than those of the K2-BVWN

calculation, however the VSCF calculation could not account for all of the COH distortions in  $\beta$ -glucopyranose (Table III). This represents a weakness in the present molecular mechanics force field.

It is well known that all sugars have characteristic C-O, C-C vibrations and CH<sub>2</sub> distortions in the region from 1200-950 cm<sup>-1</sup>.<sup>38</sup> The region from 1288 to 1100 cm<sup>-1</sup> was previously identified as the CCH out-of-plane bend as well as distortion of the HCO angles.<sup>40</sup> Modes in this region are coupled somewhat to the COH distortions. While both methods agree with the experimental frequencies, the VSCF calculation tends to underestimate the number of the CCH distortions in the range of 1130 cm<sup>-1</sup>. However, the IR spectrum of both  $\alpha$  and  $\beta$  glucopyranose from Dauchez and co-workers significantly reduces the number of CCH distortions in this region in agreement with the VSCF results.<sup>45,40</sup> We also find two frequencies [1111, 1089 ( $\alpha$ ) and 1109, 1084 ( $\beta$ -glucopyranose); 1116, 1094 ( $\alpha$ ) and 1112, 1081 ( $\beta$ -mannopyranose)] which correspond to distortions of the O<sub>5</sub> - C<sub>1</sub> bond, coupled to the COH distortions. This is in excellent agreement with the experimental evidence (D-glucose) that these frequencies are indeed O<sub>5</sub> - C<sub>1</sub> distortions.<sup>45,38</sup> The region from 1070-1000 cm<sup>-1</sup> is mainly dominated by torsions of the C-C bond along the

ring. In our calculations, we do see a very characteristic  $CH_2$  twisting motion at 946 ( $\alpha$ ), 959  $cm^{-1}$  ( $\beta$ -glucopyranose) and 918  $\alpha, \beta$ -mannopyranose. Experimentally, Korolevich et al.<sup>38</sup> calculated this twist to lie at 934  $cm^{-1}$  for  $\alpha$ -glucopyranose. While the density functional method (K2-BVWN) was not able to reproduce the frequency of the  $CH_2$  twist for  $\beta$ -D-glucopyranose, it was in reasonable agreement with the VSCF and experimental frequencies for the other sugars studied.

The molecular skeleton deformations involving the  $(C_2C_1)_t$  occur around 775 ( $\alpha$ ), 735 ( $\beta$ -glucopyranose) to 800  $cm^{-1}$  ( $\alpha, \beta$ -mannopyranose).<sup>37</sup> In the case of glucopyranose, the VSCF method overestimates this mode by 100  $cm^{-1}$ , while the K2-BVWN method underestimates it by as much as 65  $cm^{-1}$ . However, in the case of D-mannopyranose,

$\alpha$ -D-mannopyranose	5.9	4.1
$\beta$ -D-mannopyranose	4.7	3.8

a. The estimation of the error for both methods does not include the  $(OH)_s$  frequencies.

this mode poses no difficulty for either method. Below  $700\text{ cm}^{-1}$ , the hydroxyl out-of-plane modes and the ring distortions begin to dominate. In this region of the spectrum ( $650 - 400\text{ cm}^{-1}$ ), the K2-BVWN frequencies are somewhat lower than the corresponding VSCF and experimental frequencies. This could be due to the anharmonic nature of these low frequencies. Such effects are not yet accounted for in DFT-based methods. We did not attempt to assign the region below  $400\text{ cm}^{-1}$ , and in fact the experimental assignment of D-mannopyranose below  $800\text{ cm}^{-1}$  is quite subjective. We find however, that in general the K2-BVWN frequencies compare well to both the VSCF frequencies and experimental spectrum. Although the average errors for the K2-BVWN method are always slightly higher than those of the VSCF calculation, the general agreement of frequencies in the range between  $1500$  and  $900\text{ cm}^{-1}$  is quite good. The average errors for the K2-BVWN method are highest for  $\alpha$ -D-glucopyranose due in part to the large overestimation of the CH stretch. Below  $800\text{ cm}^{-1}$ , the agreement between both the K2-BVWN and VSCF calculations to the experimental frequencies falls off, and is in fact poor for the  $(O_5C_1C_2)_t$  modes ( $750 - 800\text{ cm}^{-1}$ ). We did not attempt to assign the modes below  $400\text{ cm}^{-1}$ .

## CONCLUSION

In this paper, we begin with a study of a novel density functional method (K2-BVWN) to the calculation of the energetics and spectroscopy for both  $\alpha$ ,  $\beta$ -D-glucopyranose and  $\alpha$ ,  $\beta$ -D-mannopyranose. The K2-BVWN method signifies an advancement in density functional methods in that it mixes the HF and gradient corrected local spin density exchange using the adiabatic connection formula<sup>33</sup> together with the Pade-approximated Vosko, Wilk and Nusair (VWN) correlation functional.<sup>34</sup> This new method has two attractive features, the scaling is roughly  $N^3$ , where  $N$  is the number of basis functions, and there are only two adjustable parameters. The calculation of the vibrational frequencies in the K2-BVWN method are compared to both the VSCF calculated and experimentally measured IR frequencies. In the case of the VSCF calculation, we begin with the assumption that for many of the modes in condensed systems, we can use the near separability of the normal mode degrees of freedom to reduce the fully N-dimensional coupled Hamiltonian into N-single mode equations. We further restrict the coupling between the modes to occur in a pair-wise manner, such that a quartic expansion of the potential is realized. In previous work we have illustrated that for many modes in biological systems, this approximation is

valid.<sup>46</sup> This leads to N-single mode VSCF equations which are solved in a self-consistent manner.

A comparison between previous high level *ab initio* calculations and the density functional method K2-BVWN is made in order to illustrate that the present method will compare well with higher level *ab initio* methods. The advantage of the present method is that the scaling is drastically reduced making such a method attractive for larger oligosaccharide systems. In the present study, 11 low energy conformers were chosen from the previous work of Barrows et al.<sup>9</sup> We find that in general the relative energies of the 11 conformers do follow the same trends (Table I). As in the *ab initio* calculations, the clockwise conformers are higher in energy relative to the corresponding counterclockwise conformers. Furthermore, the relative energy difference between  $\alpha/\beta$  pairs (either clockwise or counterclockwise) is roughly 0.8 kcal/mol (counterclockwise) and 1.98 kcal/mol (clockwise). This is in agreement with the *ab initio* results at the MP2/cc-pVDZ level of theory. The only difference between the two results, the K2-BVWN method would predict the  $G^+$  conformer number 7 to be the lowest energy conformer as opposed to the  $G^-$  conformer number 8 low energy *ab initio* structure. Finally, a very rough estimation of the gas phase free energy difference between  $\alpha$  and  $\beta$ -D-glucopyranose is made using the rovibrational contributions to the free energy of Barrows and co-workers.<sup>9</sup> We estimate the free energy of  $\alpha \rightarrow \beta$  anomerization at 298 K to be roughly between 0.0 to 0.5 kcal/mol in favor of the  $\alpha$  anomer. This would be within the *ab initio* calculated range of 0.4 kcal/mol.

We also find that in general a comparison between the VSCF and K2-BVWN frequencies is quite good in the region between 1500 and 900  $\text{cm}^{-1}$ . The average error of the calculations compared to the experimental frequencies are slightly larger for the K2-BVWN method compared with the VSCF method. This is due in part to an overestimation of the *CH* stretching frequency, and an underestimation of the hydroxyl out-of-plane modes in the K2-BVWN calculation. In general we also find that the VSCF frequencies are blue shifted somewhat compared to the K2-BVWN frequencies due to the inclusion of the anharmonic and mode coupling effects in the VSCF method. At present it is not possible to include these effects into the K2-BVWN calculation.
