# Ethylene + Olefin Binary Systems: Vapor-Liquid Equilibrium Experimental Data and Modeling 

Serge Laugier, ${ }^{\dagger}$ Dominique Richon, and Henri Renon*

Laboratoire de Thermodynamique, Centre Réacteurs et Processus, Ecole Nationale Supérieure des Mines de Paris, 35 rue Saint-Honoré 77305 Fontainebleau, France

#### Abstract

New data on ethylene +1 -butene, 1 -hexene, or 1 -octene binary systems were obtained at different temperatures (around 293,332 , and 373 K ) up to 9 MPa . Data on the ethylene +1 -butene system are compared to those from Bae et al. (1). Experimental data are represented using the Peng-Robinson equation of state and one adjusted binary interaction parameter.

## Introduction

High-pressure vapor-liquid equilibrium data are required for plant design and for theoretical purposes such as checking the efficiency of the equations of state. Therefore, reliable data must be obtained. In order to check for systematic errors, our laboratory has designed and constructed several apparatus which are different in their basic principles (analytic and synthetic methods). In this work three apparatus have been used to obtain the new data, and consistent results were obtained.

## Experimental Section

Apparatus. The three apparatus used to carry out the measurements in isothermal conditions at given temperatures were the following: Apparatus $I$ is an apparatus based on a static method with sampling of both phases using valves as described by Figuiere et al. (2) and Laugier (3). Apparatus II, also based on a static method, uses special pneumatic capillary samplers (4). Apparatus III is based on a synthetic method; a variable-volume cell yields the bubble pressure; the overall composition of the loaded mixture is known through accurate weighings (5).

The reason for using three different measurement techniques, two of the analytic static type (apparatus I and II) differing only by the sampling method and one of the synthetic type, is to check for any possibility of systematic error and to benefit from the advantages of each method: faster measurements with the analytic method, higher accuracy in the synthetic method.

Due to small residence times, polymerization was negligible.
Chemicals. Ethylene was provided by CDF Chimie (Dunkerque plant). 1-Butene, purum ( $>99.3 \%$ ), is from Hüls. 1-Hexene, purum ( $>99 \%$ ), and 1-octene, purum ( $>99 \%$ ), are from Ethyl-Corp. All these products have the polymer grade label. All compounds were used without any further purification except for a careful degassing of the liquids.

## Results

Experimental results for the three binary systems are

[^0]

Figure 1. Pressure as a function of ethylene mole fraction in the ethylene (1) + 1-butene ( 2 ) system at different temperatures: Bae et al., $273 \mathrm{~K}(\times), 283 \mathrm{~K}(+), 293 \mathrm{~K}\left({ }^{*}\right)$; this work, 293 K ( O , analytic method; ©, synthetic method), 333 K ( $\square$, analytic method; $\boldsymbol{\square}$, synthetic method), $375 \mathrm{~K}(\diamond) ;(-)$ calculated results with the PR-EoS and $\delta_{i j}$ $=0$.
reported in Tables 1-3 and displayed in Figures 1-6. Figures 1,3 , and 5 show phase envelopes and Figures 2, 4, and 6 partition coefficients (symbols are experimental data, while solid curves are calculated data). Estimates of experimental errors are given in the tables. $\sigma_{x}$ and $\sigma_{y}$ are calculated from uncertainties in GLC detector calibrations and dispersions observed on analyses of at least five samples.

Data modeling was performed using several equations of state: the Redlich-Kwong-Soave equation of state (RKSEoS) (6), the Peng-Robinson equation of state (PR-EoS) (7),

Figure 6. Partition coefficients as a function of pressure in the ethylene (1) +1 -octene (2) system at different temperatures: $303 \mathrm{~K}(\mathrm{O}) ; 342 \mathrm{~K}(\square)$; ( - calculated results with the PR-EoS and $\delta_{i j}=0.011$.
in Table 5. These binary interaction parameters were adjusted on data from this work using the objective function

$$
\begin{equation*}
Q=\sum_{j=1}^{n}\left(\frac{P_{j, \text { exptl }}-P_{j, \text { calce }}}{P_{j, \text { exptl }}}\right)^{2}+\left(\frac{y_{1, \text { exptl }}-y_{1 j, \text { caled }}}{y_{1, \text {,exptl }}}\right)^{2} \tag{3}
\end{equation*}
$$

The optimum values are listed for each mixture for the PR
and RKS equations of state. Representations are equivalent with the gTBS equation of state while the gPT equation of state is only slightly worse.
Data from Bae et al. (1) are compared to those of the present work in Figures 1 and 2. In Figure 2, we may notice that their data are in relatively good agreement with ours except at high pressures. Data from Bae et al. at the lowest temperature are very dispersed with an erroneous point. Solid curves obtained using PR-EoS and $\delta_{i j}$ adjusted on our data (see Table 5) represent both sets of data well. $\delta_{i j}$ adjusted on Bae et al.'s data is very small (close to zero). The average relative deviation on Bae et al.'s pressure data is about 2.5 higher than on our data.

## Acknowledgment

We thank other co-workers, A. Chareton and A. Valtz, who took part in the measurements.
