

Vapor Pressures, Gas-Phase PVT Properties, and Second Virial Coefficients for 1,1,1-Trifluoroethane

Heng-Liang Zhang,* Haruki Sato, and Koichi Watanabe

Department of Mechanical Engineering, Faculty of Science and Technology, Keio University, 3-14-1 Hiyoshi, Kohoku-ku, Yokohama 223, Japan

The PVT properties of 1,1,1-trifluoroethane (R-143a) in the gas phase have been measured by a Burnett apparatus in the range of temperatures from 320 to 380 K and at pressures up to 6 MPa. The vapor pressures in the range of temperatures from 295 to 342 K have also been measured, and a vapor-pressure correlation has been developed. The critical pressure was determined to be (3.776 ± 0.005) MPa on the basis of the present measurements. The second virial coefficients have been determined along seven isotherms, and a truncated virial equation of state has also been developed to represent the temperature dependence of the second virial coefficients and the present Burnett PVT measurements. The experimental uncertainties of temperature, pressure, density, and second virial coefficient throughout the present study were estimated to be no more than ± 8 mK, ± 0.8 kPa, $\pm 0.12\%$, and $\pm 5\%$, respectively. The purity of the R-143a sample used was better than 99.95 mol %.

Introduction

1,1,1-Trifluoroethane (R-143a) has zero ozone depletion potential, but it is flammable. Therefore, it has recently been proposed to use this substance in refrigeration applications as a component of promising alternative refrigerant mixtures with other HFC refrigerants such as difluoromethane (R-32), pentafluoroethane (R-125), and/or 1,1,1,2-tetrafluoroethane (R-134a). Concerning its thermodynamic properties, vapor pressures and second virial coefficients were reported in the literature (Beckermann and Kohler, 1994; Fukushima, 1993; Russell et al., 1944; Widiatmo et al., 1994; Ye, 1993), but very few PVT results are available.

In this paper, we report vapor pressures and PVT properties for R-143a. The measurements have been performed by a Burnett apparatus whose operating performance and reliability were well established through our previous measurements for other alternative refrigerants including R-134a (Qian et al., 1992), R-32 (Qian et al., 1993), and R-125 (Ye et al., 1995). The second virial coefficients have been determined along seven isotherms, and a truncated virial equation of state and a vapor-pressure correlation have also been developed to represent the present measurements.

Experimental Section

The Burnett apparatus used in the present measurements is schematically shown in Figure 1. It consists of a cell system, a temperature control and measuring system, a pressure measuring system, and a vacuum discharge system. The cell system consists of two cells, a sample cell (A) and an expansion cell (B), and an expansion valve (V1). The two cells, which are thick-walled spherical vessels made of SUS-304 with about 500 and 250 cm³ in their respective inner volumes, are connected by the expansion valve, a constant-volume valve that avoids any noxious volume change during valve operation. For the purpose of establishing a uniform temperature around the two cells and the diaphragm-type differential pressure detector (C), they are all coupled together and immersed in a thermostated oil bath (I) using silicone oil as a heat transfer medium.

Figure 1. Burnett experimental apparatus: (A) sample cell; (B) expansion cell; (C) differential pressure detector; (D) platinum resistance thermometer; (E) stirrer; (F) main heater; (G) sub-heater; (H) cooler; (I) constant temperature bath; (J) N₂ bottle; (K) N₂ gas damper; (L) hand piston; (M, N) Digiquartz pressure transducer with temperature sensor; (O) thermometer bridge; (P) pen recorder; (Q) voltage/current converter; (R) PID controller; (S) dc power supply; (T) digital pressure gauge; (V1) constant volume valve; (V1-V15) valves.

The temperature was controlled by means of a PID controller and was measured by a standard platinum resistance thermometer installed near the cells. The platinum resistance thermometer was calibrated at the National Research Laboratory of Metrology, Tsukuba, and the uncertainty of the temperature measurements was estimated to be ± 8 mK, the sum of ± 2 mK for the uncertainty of the thermometer, ± 1 mK for the uncertainty of the thermometer bridge, and ± 5 mK for the possible temperature fluctuation of the thermostated bath. The temperature was then calculated on the basis of the International Temperature Scale of 1990 (ITS-90).

The sample pressure was transmitted to an external pressure measuring system through the differential pres-

sure detector (C). By balancing the sample gas pressure with the nitrogen gas pressure in the pressure measuring system, the nitrogen gas pressure was directly measured by a Digiquartz pressure transducer gauge (M or N). One of them (M) was used for pressure measurements above 1.1 MPa, while the other (N) was used for pressures below 1.1 MPa. The experimental uncertainty in the pressure measurements was estimated to be no more than ± 0.8 kPa, which consists of the reproducibility of the differential pressure measurements, ± 0.5 kPa, and the accuracy of the pressure gauge, ± 0.3 kPa, which includes the uncertainties of the correction for the hydrostatic pressure difference of nitrogen gas.

Accurate determination of the cell constant, which is the ratio of the two different volumes of cell A and cells A and B at zero pressure, is one of the essential factors in the Burnett method. By using gaseous helium whose thermodynamic properties are well established (*International Thermodynamic Tables of the Fluid State-Helium*, 1977), the cell constant, $N = 1.50368 \pm 0.00019$, was accurately determined by Qian et al. (1992).

The purity of the R-143a sample used in the present measurements was 99.95 mol % according to the analysis performed by the chemical manufacturer.

Results

Vapor Pressures. We measured the vapor pressures of R-143a by filling the sample cell to approximately the critical density. A total of 11 vapor-pressure values were obtained at temperatures from 295 to 342 K that correspond to the pressures from 1.16 to 3.47 MPa. The vapor pressure values are tabulated in Table 1.

PVT Properties. The Burnett expansion measurements were performed at temperatures from 320 to 380 K. A total of 84 compressibility factors for R-143a have been measured by 9 independent series of expansion. In addition, eight PVT property values have also been obtained along an isochore ($\rho = 0.6534 \text{ mol}\cdot\text{L}^{-1}$) by a coupled isochoric-expansion procedure. Figure 2 summarizes the measured PVT points which cover the range of temperatures of 320–380 K, pressures of 0.11–6.0 MPa, and densities of 0.04–7.39 $\text{mol}\cdot\text{L}^{-1}$. Note that two different symbols (\circ and \bullet) represent two independent series of expansion which have been performed along two isotherms (350 and 370 K) for the purpose of examining the reproducibility of the present measurements.

The PVT data were analyzed with the cell constant mentioned above. The experimental pressures, P , temperatures, T , the compressibility factors, Z , and the calculated densities, ρ , are given in Table 2.

Second Virial Coefficients. The second virial coefficients, B , have been determined from the PVT data along different isotherms in the low-density region by calculating $(Z - 1)/\rho$ as a function of density, ρ . In consideration of the experimental uncertainties, the following expression with three coefficients was used to fit the measured compressibility-factor data:

$$(Z - 1)/\rho = B + C\rho + D\rho^2 \quad (1)$$

As a typical example, the dependence of $(Z - 1)/\rho$ on ρ along the 370 K isotherm is shown in Figure 3. The experimental

Figure 2. Distribution of the experimental PVT data for R-143a; \circ , series 1 for 350 and 370 K isotherms; \bullet , series 2 for 350 and 370 K isotherms; +, isochore ($\rho = 0.6534 \text{ mol}\cdot\text{L}^{-1}$); *, critical point.

uncertainties, ± 0.8 kPa for pressure and ± 8 mK for temperature measurements, have been added as an error bar to each data point in Figure 3. The intercept with the ordinate gives the second virial coefficient, B . Using the same procedure, a total of seven second virial coefficient values have been determined, and they are tabulated in Table 3. The uncertainty of the second virial coefficients determined by the present study was estimated to be no more than $\pm 5\%$ on the basis of the compressibility-factor uncertainty and the data scatter.

It should be noted that, in Figure 3, the two independent series of measurements along the 370 K isotherm show a very consistent behavior. Since a similar consistent behavior by two independent series of measurements has also been observed along the 350 K isotherm, the reproducibility of the present measurements has been confirmed.

Discussion

Vapor Pressures. The 11 experimental vapor-pressure data given in Table 1 were correlated with the following functional form:

$$\ln(P/P_c) = [-7.33064(1 - T_r) + 1.53338(1 - T_r)^{1.5} - 3.16056(1 - T_r)^3]/T_r \quad (2)$$

where P and P_c denote the vapor pressure and the critical pressure, T_r denotes the dimensionless temperature defined by $T_r = T/T_c$, and T and T_c denote the temperature and the critical temperature. The value used for T_c is (345.97 ± 0.03) K which was determined by Fukushima (1993).

The input data for developing the vapor-pressure correlation, eq 2, include the present measurements for temperature 295–342 K, and nine data for 174–226 K reported by Russell et al. (1944). The critical pressure, P_c , in eq 2 has been determined to be (3.776 ± 0.005) MPa in fitting the input data so as to be consistent with the critical temperature mentioned above. Equation 2 is effective for the range of temperatures from 174 K to the critical temperature.

All of the vapor-pressure data measured by this work, Russell et al. (1944), Fukushima (1993), Widiatmo et al. (1994), and Ye (1993), were compared with eq 2 in Figure 4. The absolute deviation of the vapor pressures measured by the present study from eq 2 is less than ± 1.0 kPa, which is slightly greater than the accuracy of the pressure measurements (± 0.8 kPa). If the uncertainty of the present temperature measurements (± 8 mK) is also taken into account, however, then the agreement should be

considered acceptable. The deviations of the reported data (Fukushima, 1993; Russell et al., 1944; Widiatmo et al., 1994; Ye, 1993) from the equation are random, and are approximately within the claimed uncertainty of each measurement.

Table 3. Second Virial Coefficients of R-143a

T/K	$B/(\text{cm}^3\cdot\text{mol}^{-1})$	T/K	$B/(\text{cm}^3\cdot\text{mol}^{-1})$
320.000	-345.5	360.000	-257.0
330.000	-320.4	370.000	-239.5
340.000	-295.7	380.000	-224.1
350.000	-274.1		

Second Virial Coefficients. The temperature dependence of the second virial coefficients given in Table 3 is represented by

$$B = 4.33476 \times 10^{-1} + 6.09455 \times 10^{-1} T_r^{-1} - 4.87858 \times 10^{-1} \exp(T_r^{-1}) \quad (3)$$

where B is given in liters per mole. In Figure 5, the B values by Beckermann and Kohler (1994) obtained from acoustic measurements are compared with eq 3 and the present data. Although the values by Beckermann and Kohler are systematically higher than the present results, the two different measurements show agreement within 2%. Equation 3 represents the second virial coefficient data given in Table 3 within $\pm 0.33\%$.

Virial Equation of State. In order to facilitate calculation of the thermodynamic properties, we have developed a truncated virial equation of state. This was done by

Figure 4. Vapor-pressure deviations from eq 2: \blacklozenge , Russell et al. 1944; \triangle , Ye 1993; \square , Widiatmo et al. 1994; $*$, Fukushima 1993; \bullet , this work; $-$, eq 2.

Figure 5. Temperature dependence of the second virial coefficient: \triangle , Beckermann and Kohler (1994); \circ , this work; $-$, eq 3.

fitting the data given in Table 2 with the following function:

$$Z = 1 + B\rho + C\rho^2 + D\rho^3 \quad (4)$$

where

$$Z = P/(\rho RT)$$

$$C = c_1 T_r^{-1} + c_2 T_r^{-3} + c_3 T_r^{-5}$$

$$D = d_1 T_r^{-2} + d_2 T_r^{-5.5}$$

B is expressed by eq 3, T is in kelvin, ρ in moles per liter, P in kilopascals, R is the universal gas constant ($8.314\,510\,7\text{ J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$), $c_1 = -2.78455 \times 10^{-2}$, $c_2 = 9.30967 \times 10^{-2}$, $c_3 = -2.88435 \times 10^{-2}$, $d_1 = -0.474641 \times 10^{-3}$, and $d_2 = -1.40684 \times 10^{-3}$. This equation is effective for the range of temperatures from 320 to 380 K, for pressures up to 4.6 MPa, and for densities up to $3.5\text{ mol}\cdot\text{L}^{-1}$.

The pressure deviations of the present data from eq 4 are shown in Figure 6. Excluding several points in the higher density region, eq 4 represents the data given in Table 2 within $\pm 0.2\%$. It should be noted that, as shown in Figure 6, the isochoric data (symbol +) do not show any significant difference from those measured along isotherms. It has also been confirmed, therefore, that the present measurements are self-consistent.

Conclusions

We have measured 11 vapor pressures for temperatures from 295 to 342 K and 92 PVT data for temperatures from

Figure 6. Pressure deviations of the experimental PVT data from eq 4: \diamond , 320 K; \triangle , 330 K; \square , 340 K; \times , 350 K; $*$, 360 K; \circ , 370 K; $+$, isochore ($\rho = 0.6534\text{ mol}\cdot\text{L}^{-1}$); $-$, eq 4.

320 to 380 K at pressures up to 6.0 MPa for R-143a. On the basis of these vapor-pressure measurements, a vapor-pressure correlation has been developed and the critical pressure has been determined as $P_c = (3.776 \pm 0.005)\text{ MPa}$. Throughout the present analysis of the Burnett measurements, the second virial coefficients of R-143a have been determined over the measured range of temperatures, and a truncated virial equation of state which is effective for gaseous R-143a has also been developed.

Acknowledgment

We acknowledge Daikin Industries, Osaka, for kindly furnishing the sample of R-143a. We also thank M. Miyamoto, an undergraduate student at Keio University, for his valuable assistance in this work.
