# Theoretical Calculation of Thermodynamic Properties of Polybrominated Dibenzo-p-dioxins 

Xian-Wei Li,* Etsuro Shibata, and Takashi Nakamura

Institute of Multidisciplinary Research for Advanced Material, Tohoku University, 1,1 Katahira, 2-Chome, Aobaku, Sendai 980-8577, J apan

#### Abstract

Heat capacities and entropies for 76 polybrominated dibenzo-p-dioxins (PBDDs) in the gas state at 298.15 K and 101.325 kPa have been computed using the density functional theory (B3LYP/6-31G(d)) with Gaussian 98. Based on the output data of Gaussian, three methods were empl oyed to cal culate enthalpies and Gibbs energies of formation of the 76 PBDDs in the gaseous state at 298.15 K and 101.325 kPa . To assess the three methods, thermodynamic properties of 16 compounds were first calculated by B3LYP/ $6-31 \mathrm{G}(\mathrm{d})$ and compared with reference values. F or predicting the enthal pies of formation of the reference compounds, method 2 has the smallest average absolute deviation from the experimental data. All values for the heat capacity, entropy, enthalpy, and energy of formation of the 76 PBDDs increase as the number of substituted bromines increases. For isomers of tetrabromodibenzo-p-dioxins, 1,3,6,8-TeBDD, 1,3,7,8TeBDD, $1,3,7,9-\mathrm{TeBDD}$, and the most toxic compound $2,3,7,8-\mathrm{TeBDD}$ are more stable than the others and easier to form during the formation process.

## 1. Introduction

Polybrominated dibenzo-p-dioxins (PBDDs) and polybrominated di benzofurans (PBDFs) can beformed by chemical, photochemical, or thermal reactions from precursors and by so-called de novo synthesis. PBDDs and PBDFs have been found as contaminants in brominated organic chemicals and, in particular, in flame retardants: polybrominated diphenyl ethers (PBDEs), decabromobiphenyl (decaBB or DBB), 1,2-bis(tribromophenoxy)ethane, tetrabromobisphenol A (TBBPA), and others. They have been detected in distillation residues of some bromophenols and bromoanilines and in wastes from chemical laboratories. Brominated flame retardants and their precursors appear to be a main source of PBDDs and PBDFs.

As conduded by the World Health Organization (WHO), the potential of PBDDs and PBDFs for biological (e.g., enzyme induction) and toxic effects is similar to that of the polychlorodibenzo-p-dioxins (PCDDs) and polychlorodibenzofurans (PCDFs). PBDDs and PBDFs are contaminants that are more or less similar to PCDDs and PCDFs in their persistence and toxicity. ${ }^{1}$

There is much less information on PBDDs and PBDFs than on their chlorinated analogues, and there are very few experimental data on their physical and chemical properties. The analytical methods for separating and identifying the individual brominated congeners are much less advanced than those for their chlorinated analogues, and only few reference standards are available. Current analytical methods are able to quantify total brominated homologue groups and also to detect but not quantify the mixed brominated/chlorinated congeners. Because of the complexity of analytical procedures, it has been possible to characterize and determine only a small number of PBDD/Fs and PXDD/Fs, and only a few of the compounds have CAS registry numbers.

In this study, the thermodynamic properties (heat capacity, entropy, and Gibbs energy of formation) in the gaseous

[^0]state at 298.15 K and 101.325 kPa were computed for all 76 PBDDs using density functional theory (DFT) with Gaussian 98 programs. ${ }^{2}$ The purpose of the study was to obtain a consistent set of thermodynamic values for PBDDs. The discrepancy between the calculated results and available experimental values for 16 compounds (brominated arenes) is also discussed. The present thermodynamic data are, to our knowledge, the first set of calculated data reported on PBDDs.

## 2. Computational Methods

Becke's three-parameter hybrid functional combined with the gradient-correlation functional of Lee, Yang, and Parr (LYP), denoted B3LYP, was employed in the computations using DFT. The all-electron 6-31G(d) basis set was employed. Geometries were optimized using analytic gradient techniques, that is, the Berny algorithm with redundant internal coordinates. The stationary points on the potential energy surface were characterized by calculations of vibrational frequencies, which were done analytically at DFT levels. F ollowing the geometry optimization, frequencies were calculated using the same method at a stationary point. The zero-point vibrational energies (ZPE) cal culated at the DFT Ievel were scaled by $0.9804 .^{3}$

Throughout this paper, all calculations for PBDDs were carried out with B3LYP/6-31G(d) Opt Freq. This computational model level is different from those which have been applied to calculate the thermodynamic values of dioxin congeners serially. ${ }^{4-6}$
The equations used for computing thermochemical data in Gaussian programs are derived from statistical thermodynamics. Two key ideas of statistical thermodynamics are the Boltzmann distribution and the partition function. The partition function is like a thermodynamic wave function, in the sense that it contains all thermodynamic information about the system, just as the quantum mechanical wave function contains all dynamic information.
2.1. Entropy and Heat Capacity. The entropy and heat capacity can be directly obtained from the output of

a Chase, 1998 (ref 15).
Gaussian programs. The equations used for computing thermochemical data in the programs are equivalent to those given in statistical mechanics texts. ${ }^{7,8}$
2.2. Enthalpy and Gi bbs Energy of Formation. The following equations are employed to calculate the absolute internal energy (U), enthalpy (H), and Gibbs energy (G) of the molecule at zero Kelvin and the specified temperature (T): ${ }^{7-9}$

$$
\begin{gather*}
\mathrm{U}_{\mathrm{OK}}=\mathrm{E}_{\text {elec }}+\mathrm{E}_{\text {zpe }}  \tag{1}\\
\mathrm{U}_{\mathrm{T}}=\mathrm{U}_{\mathrm{OK}}+\left(\mathrm{E}_{\text {trans }}+\mathrm{E}_{\text {rot }}+\mathrm{E}_{\mathrm{vib}}\right)_{\mathrm{T}}  \tag{2}\\
\mathrm{H}_{\mathrm{T}}=\mathrm{U}_{\mathrm{T}}+\mathrm{RT}  \tag{3}\\
\mathrm{G}_{\mathrm{T}}=\mathrm{H}_{\mathrm{T}}-\mathrm{TS} \tag{4}
\end{gather*}
$$

where $E_{\text {elec }}$ is the internal energy due to electronic motion and $E_{\text {zpe }}$ the zero point energy of the molecule at 0 K (a correction to the el ectronic energy). $\mathrm{E}_{\text {trans }}, \mathrm{E}_{\text {rot }}$, and $\mathrm{E}_{\text {vib }}$ are the thermal energy corrections due to the effects of molecular translation, rotation, and vibration at the specified temperature, respectively.

In this study, $\mathrm{E}_{\text {elec }}$ is computed at the B3LYP level. $\mathrm{E}_{\text {trans, }}$ $E_{\text {rot, }}$ and $E_{\text {vib }}$ can be rapidly calculated using statistical thermodynamics. All the values of $E_{\text {elec }}, E_{\text {zpe }}, U_{T}, H_{T}$, and $\mathrm{G}_{\mathrm{T}}$ are given in hartrees (atomic units, 1 hartree $=2625.51$ $\mathrm{kJ} \cdot \mathrm{mol}^{-1}$ ) by the output of the program.

On the basis of these absolute energy values, enthalpy and Gibbs energy of formation can be calculated by different methods.
2.2.1. Method 1. The enthal pies of formation at 0 K were calculated by subtracting the calculated atomization energies $\left(\sum D_{0}\right)$ from the known enthal pies of formation of the isolated atoms. The enthal pies of formation at 298.15 K were calculated by correction to the enthal pies of formation at 0 K . This method is the common theoretical method for calculating the enthal py of formation used by many studies. ${ }^{6,9-11}$

F or the computation of enthal pies of formation, Curtiss et al. ${ }^{11}$ tested seven density functional methods: B3LYP, BP86, B3P86, BPW91, B3PW91, and SVWN with 148 molecules. Of these seven DFT methods, the B3LYP method has the smallest average absolute deviation (13.0 $\mathrm{kJ} \cdot \mathrm{mol}^{-1}$ ) from the experimental values.

The calculation procedure is as follows:

$$
\begin{gather*}
\Delta_{\mathrm{f}} \mathrm{H}^{\circ}(\mathrm{M}, 0 \mathrm{KK})=\sum \mathrm{x} \Delta_{\mathrm{f}} \mathrm{H}^{\circ}(\mathrm{X}, 0 \mathrm{~K})-\sum \mathrm{D}_{0}(\mathrm{M})= \\
\sum \mathrm{x} \Delta_{\mathrm{f}} \mathrm{H}^{\circ}(\mathrm{X}, 0 \mathrm{OK})-\left[\sum \mathrm{xU}(\mathrm{X}, 0 \mathrm{~K})-\mathrm{U}(\mathrm{M}, 0 \mathrm{~K})\right]  \tag{5}\\
\Delta_{\mathrm{f}} \mathrm{H}^{\circ}(\mathrm{M}, 298 \mathrm{~K})=\Delta_{\mathrm{f}} \mathrm{H}^{\circ}(\mathrm{M}, 0 \mathrm{~K})+\left[\mathrm{H}^{\circ}(\mathrm{M}, 298 \mathrm{~K})-\right. \\
\left.\mathrm{H}^{\circ}(\mathrm{M}, 0 \mathrm{~K})\right]-\sum \mathrm{x}\left(\mathrm{H}_{298 \mathrm{~K}}-\mathrm{H}_{0 \mathrm{~K}}\right)_{\mathrm{X}}  \tag{6}\\
\Delta_{\mathrm{f}} \mathrm{G}^{\circ}(\mathrm{M}, 298 \mathrm{~K})=\Delta_{\mathrm{f}} \mathrm{H}^{\circ}(\mathrm{M}, 298 \mathrm{~K})-\mathrm{T} \Delta \mathrm{~S}= \\
\Delta_{\mathrm{f}} \mathrm{H}^{\circ}(\mathrm{M}, 298 \mathrm{~K})-\mathrm{T}\left[\mathrm{~S}^{\circ}(\mathrm{M}, 298 \mathrm{~K})-\sum \mathrm{xS}{ }^{\circ}(\mathrm{X}, 298 \mathrm{~K})\right] \tag{7}
\end{gather*}
$$

where $\Delta_{\mathrm{f}} \mathrm{H}^{\circ}$ and $\Delta_{\mathrm{f}} \mathrm{G}^{\circ}$ are the standard-state enthal py and Gibbs energy of formation of the ideal gas, respectively. M stands for the molecule of the compound, X identifies each element which composes $M$, and $x$ is the stoichiometric
coefficient of the constituent. $\left(\mathrm{H}_{298 \mathrm{~K}}-\mathrm{H}_{0 \mathrm{~K}}\right)_{\mathrm{x}}$ is the formation enthalpy correction from 0 K to 298 K for elements in the reference state.

Dixon et al. ${ }^{12,13}$ have used high-level ab initio electronic structure theory to cal culate the heats of formation of CBr , $\mathrm{CHBr}, \mathrm{CBr}_{2}$, and other small halogenated compounds. It was found that the spin-orbit corrections must be applied to the atomization energies of these compounds, especially brominated compounds, as the atomic energies are calculated incorrectly without spin-orbit corrections. An atomic spin-orbit correction of $-3.51 \mathrm{kcal} \cdot \mathrm{mol}^{-1}\left(-14.69 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}\right)$ for Br on the basis of the excitation energy tables of M oore ${ }^{14}$ was proposed. The spin-orbit correction $\Delta \mathrm{E}_{\text {so }}$ of -14.69 $\mathrm{kJ} \cdot \mathrm{mol}^{-1}$ per Br atom was applied to the calculations of atomization energy $\left(\Sigma D_{0}\right)$ in this study.
$\Delta_{f} \mathrm{H}^{\circ}(\mathrm{X}), \mathrm{S}^{\circ}(\mathrm{X}, 298 \mathrm{~K})$, and $\left(\mathrm{H}_{298 \mathrm{~K}}-\mathrm{H}_{0 \mathrm{~K}}\right)_{\mathrm{x}}$ are tabulated in Table 1, cited from the NIST-J ANAF Thermochemical Tables. ${ }^{15}$ The absolute standard-state entropy $\mathrm{S}^{\circ}(\mathrm{X}, 298 \mathrm{~K})$ used for elemental carbon, hydrogen, bromine, and oxygen (reference state) should be (5.740, 130.680/2, 152.206/2, and 205.147/2) J $\cdot \mathrm{mol}^{-1} \cdot \mathrm{~K}^{-1}$, respectively, not the values cited in Ochterski's paper ${ }^{9}$ (not in the reference state).
The calculated thermochemistry values using B3LYP/ 6-31G(d) for C, $\mathrm{H}, \mathrm{Br}, \mathrm{O}, \mathrm{H}_{2}, \mathrm{Br}_{2}, \mathrm{CH}_{4}, \mathrm{CH}_{3} \mathrm{Br}, \mathrm{C}_{6} \mathrm{H}_{6}, \mathrm{C}_{6} \mathrm{H}_{5}-$ Br , dibenzo-p-dioxin (DD), and 2,3,7,8-tetrabromodibenzo-p-dioxin (TBDD) are listed in Table 2; all values are in hartrees.

Method 1 is illustrated with the example cal culations for bromomethane and TBDD as follows:

For bromomethane $\left(\mathrm{CH}_{3} \mathrm{Br}\right)$,

$$
\begin{gathered}
\sum \mathrm{D}_{0}\left(\mathrm{CH}_{3} \mathrm{Br}\right)=\{[1 \times \mathrm{U}(\mathrm{C}, \mathrm{OK})+3 \times \mathrm{U}(\mathrm{H}, \mathrm{OK})+1 \times \\
\left.\mathrm{U}(\mathrm{Br}, \mathrm{OK})]-\mathrm{U}\left(\mathrm{CH}_{3} \mathrm{Br}, \mathrm{OK}\right)\right\}+1 \times \Delta \mathrm{E}_{\mathrm{sO}}=\{[1 \times \\

$$

$$
4.238+4 \times 12.255+2 \times 4.342)=131.8 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}
$$

2.2.2. Method 2. Using B3LYP/6-31G(d), it was found that the enthal py of formation results for benzene and DD cal culated by method 1 differ greatly from the experimental data. Therefore, a simple method, method 2, was proposed here.

Because the absolute enthalpy (H) and Gibbs energy (G) values of the molecule can be obtained through theoretical calculation, it is easy to obtain the reaction enthalpy and Gibbs energy for any reaction using these energy values by eqs 8 and 10 . In another way, the reaction enthal py and Gibbs energy can be calculated by eqs 9 and 11, respectively.

$$
\begin{gather*}
\Delta_{\mathrm{r}} \mathrm{H}^{\circ}(298 \mathrm{~K})=\sum\left(\mathrm{H}_{298 \mathrm{~K}}\right)_{\text {products }}-\sum\left(\mathrm{H}_{298 \mathrm{~K}}\right)_{\text {reactants }} \\
\Delta_{\mathrm{r}} \mathrm{H}^{\circ}(298 \mathrm{~K})=\sum\left(\Delta_{\mathrm{f}} \mathrm{H}_{298 \mathrm{~K}}^{\circ}\right)_{\text {products }}-\sum\left(\Delta_{\mathrm{f}} \mathrm{H}_{298 \mathrm{~K}}^{\circ}\right)_{\text {reactants }}  \tag{9}\\
\Delta_{\mathrm{r}} \mathrm{G}^{\circ}(298 \mathrm{~K})=\sum\left(\mathrm{G}_{298 \mathrm{~K}}\right)_{\text {products }}-\sum\left(\mathrm{G}_{298 \mathrm{~K}}\right)_{\text {reactants }}  \tag{10}\\
\Delta_{\mathrm{r}} \mathrm{G}^{\circ}(298 \mathrm{~K})=\sum\left(\Delta_{\mathrm{f}} \mathrm{G}_{298 \mathrm{~K}}^{\circ}\right)_{\text {products }}-\sum\left(\Delta_{\mathrm{f}} \mathrm{G}_{298 \mathrm{~K}}^{\circ}\right)_{\text {reactants }} \tag{11}
\end{gather*}
$$

Combining these equations and using the experimental data of enthal py and Gibbs energy of formation for $\mathrm{H}_{2}, \mathrm{Br}_{2}$, $\mathrm{CH}_{4}, \mathrm{CH}_{3} \mathrm{Br}, \mathrm{C}_{6} \mathrm{H}_{6}, \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Br}$, and DD, ${ }^{15-19}$ the unknown enthalpy and Gibbs energy of formation of TBDD can be
calculated from the three reactions shown in Chart 1 (all reactants and products are in the gas state).

The average values of enthalpy and Gibbs energy of formation of TBDD calculated from reactions I, II, and III are $64.3 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ and $144.4 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$, respectively.
2.2.3. Method 3 (Benson's Method). The third method for estimating the enthal pies of formation is consistent with the group additivity technique developed by Benson. ${ }^{20}$ It is a traditional empirical method. Benson group values have been substantially refined during the years; for example, the CHETAH program ${ }^{21}$ by ASTM International predicts thermochemical properties using a modern Benson application. The available values of group contributions to the enthalpy of formation given by CHETAH 7.3 are listed in Table 3. For TBDD,

$$
\begin{array}{r}
\Delta_{\mathrm{f}} \mathrm{H}_{\text {TBDD }}^{\circ}=4\left(\mathrm{C}_{\mathrm{b}} \mathrm{H}\right)+4\left(\mathrm{C}_{\mathrm{b}} \mathrm{Br}\right)+4\left[\mathrm{C}_{\mathrm{b}}-(\mathrm{O})\right]+ \\
2\left[\mathrm{O}-\left(\mathrm{C}_{\mathrm{b}}\right)_{2}\right]+\Delta_{\text {ring }}+2 \Delta_{\text {ortho }}=4 \times 13.807+4 \times \\
44.769+4 \times(-3.766)+2 \times(-78.659)+8.368+2 \times \\
3.138=76.6 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}
\end{array}
$$

## 3. Results and Discussion

To assess the accuracy of the three methods used to predict the enthalpy and Gibbs energy of formation, the thermodynamic properties of 16 compounds (brominated arenes) were first calculated and compared with available experimental data.
3.1. Discrepancy Analysis for the Computation of Thermodynamics. For brominated arenes, in fact, only minimal experimental thermodynamic data are available. Table 4 shows the calculation results of $U, G, H, S, C_{p}$, $\Delta_{\mathrm{f}} \mathrm{H}$, and $\Delta_{\mathrm{f}} \mathrm{G}$ for benzene, bromobenzenes, benzoic acid, bromobenzoic acids, naphthalene, and bromonaphthalenes in the standard-state ideal gas at 298.15 K and 101.325 kPa.

As shown, the calculated results of heat capacity and absolute entropy are in good agreement with experimental data, although few such data are available. On the properties of heat capacity and absolute entropy, the calculation results obtained by B3LYP/6-31G(d) seem to be accurate, since Gaussian employs the mature theoretical methods of statistical thermodynamics to compute these two thermodynamic properties, and this computational level is moderate.

When the enthalpy of formation is calculated for those compounds, the results by method 1 differ from the experimental values. The absolute deviations arefrom 23.5 to $59.6 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$, and the average deviation is $41.3 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$. The reason is that the model chemistry (B3LYP/6-31G(d))

${ }^{a}$ CHETAH 7.3, 2002 (ref 21).
employed due to the tradeoff of accuracy and cost is not accurate enough for the absolute internal energy calculation.

The enthalpy of formation values cal culated using method 2 are in good agreement with the experimental data of reference compounds. The average absolute deviation from experimental values by method 2 is $4.8 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$, and the largest absolute deviation is $20.3 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$.

The predicted values using method 3 are also in reasonable agreement with the experimental data. The average absolute deviation from experimental values for method 3 is $9.8 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$, and the largest absolute deviation is 27.0 $\mathrm{kJ} \cdot \mathrm{mol}^{-1}$.

Table 4 shows that the deviations in predicting the enthal pies of formation of 2,4,6-tribromoaniline and 2,4,6tribromophenol by method 2 are larger than those of the other compounds by the same method. Allot and Finch 25 reported the experimental enthal pies of formation: (159.0 $\pm 2.6) \mathrm{kJ} \cdot \mathrm{mol}^{-1}$ for $2,4,6-\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{Br}_{3} \mathrm{NH}_{2}$ and ( $-0.9 \pm 2.5$ ) $\mathrm{kJ} \cdot \mathrm{mol}^{-1}$ for $2,4,6-\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{Br}_{3} \mathrm{OH}$; at the same time, they gave theestimated $\Delta_{f} \mathrm{H}^{\circ}:(155.5 \pm 12.5) \mathrm{kJ} \cdot \mathrm{mol}^{-1}$ for $2,4,6-\mathrm{C}_{6} \mathrm{H}_{2^{-}}$ $\mathrm{Br}_{3} \mathrm{NH}_{2}$ and $(-28.0 \pm 12.5) \mathrm{kJ} \cdot \mathrm{mol}^{-1}$ for $2,4,6-\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{Br}_{3} \mathrm{OH}$ using the Cox scheme. ${ }^{31}$ The estimated value for $2,4,6-\mathrm{C}_{6} \mathrm{H}_{2^{-}}$ $\mathrm{Br}_{3} \mathrm{OH}$ by Allot and F inch is close to the value by this study
but differs from the experimental value. Unfortunately, only one experimental value is available.

For predictions of the enthalpies of formation of 2,4,6$\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{Br}_{3} \mathrm{NH}_{2}$ and $2,4,6-\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{Br}_{3} \mathrm{OH}$, the absolute deviations by method 3 are $27.0 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ and $3.7 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$, respectively. Method 3 assumes that each substitution of Br for H on the benzene ring produces an increment of 7.4 $\mathrm{kcal} \cdot \mathrm{mol}^{-1}\left(31.0 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}\right)$ in $\Delta_{\mathrm{f}} \mathrm{H}^{\circ}$. However, the experimental data show that the energy increment per Br substitution is $31.8 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ for $2,4,6-\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{Br}_{3} \mathrm{OH}$ and 24.0 $\mathrm{kJ} \cdot \mathrm{mol}^{-1}$ for $2,4,6-\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{Br}_{3} \mathrm{NH}_{2}$, although the only difference between the two compounds is an $\mathrm{NH}_{2}$ versus an OH group.

The results show that the traditional Benson's method of group additivity (method 3) is still one of the most accurate methods for estimating formation enthalpy, and the calculation process is very simple and fast.

However, Benson's method can only give a very rough correction for cis-trans isomerization empirically. In estimating the enthalpies of isomers, method 2 is superior to Benson's method, although methods 1 and 2 are far more computationally expensive.

Compared with the selected experimental data, method 2 has the smallest absolute deviation among the three

${ }^{\text {a }}$ Barin, 1989 (ref 29). ${ }^{\text {b }}$ Thermodynamics Research Center, 1997 (ref 30). c Experimental values, CHETAH 7.3, 2002 (ref 21). d Reference 18. ${ }^{\mathrm{e}}$ Reference 19. ${ }^{\dagger}$ Reference 24. ${ }^{9}$ Reference 26. ${ }^{\mathrm{h}}$ Reference 27.
methods under the condition of B3LYP/6-31G(d). As indicated by F oresman and Frisch, ${ }^{3}$ model chemistries that are known to be quite reliable for optimizing geometries can be quite poor at predicting absolute thermochemical properties, but such methods could be quite accurate at predicting other molecular properties, vibrational frequencies, and a variety of relative energy values: energy differences to similar molecules, reaction energies, and so on. The main reason method 2 can offer more accurate results is that the systematic errors in the method often cancel out across the systems being compared. Another reason is due to its use of experimental values as benchmarks.
3.2. Calculation Results of the Thermodynamic Properties of PBDDs. The calculation results of $U, G, H$, $\mathrm{S}, \mathrm{C}_{\mathrm{p}}, \Delta_{\mathrm{f}} \mathrm{H}$, and $\Delta_{\mathrm{f}} G$ for all the 76 PBDDs in the gas phase at 298.15 K and 101.325 kPa are listed in Table 5.

As the substitute number of bromine increases, both the heat capacity and the absolute entropy of gaseous PBDDs increase.

For predicting enthalpies of formation of PBDDs, the values obtained by method 2 and method 3 are in good agreement, except heptabromodibenzo-p-dioxins and octa-bromodibenzo-p-dioxin. As the substitution number of bromine increases, the enthalpies of formation by the three methods increase. The values of Gibbs energy of formation thus have the same tendency.

The enthalpy of formation results of PBDDs predicted by method 1 are al ways much higher than those by method 2. The differences between the two methods are from 60 to $67 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$.

Because of the lack of experimental data, the corrections for cis-trans isomerization used in method 3 are very rough, and the level sequence of energies of isomers is different from that predicted by method 1 and method 2. Using free energy of formation values calculated by method 2, Figures 1-5 show dearly the differences among isomers.

Among 22 isomers of tetrabromodibenzo-p-dioxins, the Gibbs energies of 1,3,6,6-tetrabromodibenzo-p-dioxin (1,3,6,8TeBDD), 1,3,7,8-tetrabromodibenzo-p-dioxin (1,3,7,8-TeBDD), 1,3,7,9-tetrabromodibenzo-p-dioxin (1,3,7,9-TeBDD), and 2,3,7,8-tetrabromodibenzo-p-dioxin (TBDD, the most toxic compound in PBDDs) are lower than those of the other 18 isomers (see Figure 3). This means that these 4 isomers are more stable and easier to form during the formation process.

In the same way, 2,7-DiBDD and 2,8-DiBDD are easier to form than the other 8 isomers of dibromodibenzo-pdioxins. 1,3,7-TrBDD, 1,3,8-TrBDD, and 2,3,7-TrBDD are easier to form than the other 11 isomers of tribromo-dibenzo-p-dioxins. F or the isomers of pentabromodi benzo-p-dioxins, 1,2,4,6,8-PeDBB, 1,2,4,7,8-PeDBB, and 1,2,4,7,9PeDBB are easier to form than the others. For the isomers

[^1]

Figure 1. Comparison of Gibbs energies of formation of dibromodibenzo-p-dioxin isomers.

Figure 2. Comparison of Gibbs energies of formation of tribromodibenzo-p-dioxin isomers.

Figure 3. Comparison of Gibbs energies of formation of tetrabromodibenzo-p-dioxin isomers.

Figure 4. Comparison of Gibbs energies of formation of pentabromodibenzo-p-dioxin isomers.

Figure 5. Comparison of Gibbs energies of formation of hexabromodibenzo-p-dioxin isomers.
of hexabromodibenzo-p-dioxins, 1,2,4,6,7,9-HxBDD and $1,2,4,6,8,9-\mathrm{HxBDD}$ are easier to form than the others.

## 4. Conclusion

(1) Under the computing level of B3LYP/6-31G(d), method 2 has the smallest average absolute deviation and maximum absolute deviation, ( 4.8 and 20.3 ) $\mathrm{kJ} \cdot \mathrm{mol}^{-1}$, from the experimental values of formation enthal py of the reference compounds, and method 2 is simpler than method 1.
(2) Benson's method is still an accurate method for estimating thermodynamic properties, and calculation procedures are very simple and much faster than methods 1 and 2. But this method can only give much rougher corrections for cis-trans isomerization empirically. Method 2 is superior to Benson's method in predicting the formation enthalpies of isomers.
(3) All the heat capacity, entropy, enthalpy, and Gibbs energy of formation values for the 76 PBDDs increase as the substitute number of bromine increases. The values of enthalpy and Gibbs energy of formation of PBDDs calculated by method 2 are recommended.
(4) F or isomers of tetrabromodibenzo-p-dioxins, 1,3,6,8TeBDD, 1,3,7,8-TeBDD, 1,3,7,9-TeBDD, and the most toxic
compound $2,3,7,8-$ TeBDD are more stable than the others and easier to form during the formation process.
