#### Abstract

Liquid-liquid equilibrium data of three systems containing surfactant polyoxyethylene cetyl ether (with abbreviation name Brij 58) and three salts, $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{4}, \mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{4}$, and $\mathrm{KH}_{2} \mathrm{PO}_{4}$, were measured at 298.15 K . Then the binodal curves were described using two three-parameter equations and the tie lines were described using four two-parameter equations. The best equations to correlate the binodal curves and the tie lines for these systems have been reported. Additionally, the effects of the salt type on the phase diagrams have been discussed.

## Introduction

Liquid-liquid extraction utilizing aqueous two-phase systems (ATPSs) has been used to separate and purify biological products from the complex mixtures. ${ }^{1-3}$ There are three kinds of ATPSs containing polymer-polymer ATPSs, polymer-salt ATPSs, and surfactant-salt ATPSs that have been used for partitioning of biological materials. The two first kinds of ATPSs are very well-known, ${ }^{4-18}$ but surfactant-salt ATPSs scarcely are found in the literature. Recently, Xie et al. ${ }^{19}$ have studied the phase equilibria for surfactant Triton-X-$100-$ salt aqueous two-phase systems for partitioning membrane proteins. It has been shown that surfactant ATPSs have some advantages in comparison with other ATPSs such as higher content of water in phases, lower interface tension, lower cost, experimental conveniences, and ease of waste disposal and consequently shorter time for phase separation, and due to their hydrophobic property, they are useful for separation membrane proteins. ${ }^{20}$

In the present work, the liquid-liquid equilibrium (LLE) data of surfactant polyoxyethylene cetyl ether (Brij 58) and three salts, $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{4}, \mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{4}$, and $\mathrm{KH}_{2} \mathrm{PO}_{4}$, as new surfactantsalt ATPSs are presented. The obtained LLE data can be used to develop thermodynamic models. Furthermore, the effect of salt type on the LLE for these systems is investigated.

## Experimental Section

Materials. The nonionic surfactant, Brij 58 (polyoxyethylene cetyl ether), was purchased from Sigma-Aldrich Co. and used without further purification. The average ethylene oxide (EO) chain length and the average molecular weight of surfactant are 20 and $1124 \mathrm{~g} \cdot \mathrm{~mol}^{-1}$, respectively. Also, the critical micelle concentration (CMC), the hydrophilic lypophilic balance (HLB), and the melting point are $0.077 \mathrm{mg} \cdot \mathrm{L}^{-1}, 16$, and 311.15 K , respectively. ${ }^{21}$ The salts $\mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{4},\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{4}$, and $\mathrm{KH}_{2} \mathrm{PO}_{4}$ were obtained from Merck. The salts were dried at 383.15 K for 24 h . All chemicals were used without further purification.

[^0]Table 1. Coefficients of Equation 1 for System 1 (Aqueous Solution of Brij $58+\left(\mathbf{N H}_{4}\right)_{2} \mathbf{H P O}_{4}$ ), System 2 (Aqueous Solution of Brij $58+$ $\mathbf{N H}_{4} \mathbf{H}_{2} \mathbf{P O}_{4}$ ), and System 3 (Aqueous Solution of Brij $58+\mathbf{K H}_{2} \mathbf{P O}_{4}$ ) at 298.15 K

| 2 | 1.3320 | 0.1309 | 0.0018 |
| 3 | 1.3320 | 0.1311 | 0.0015 |

Apparatus and Procedure. A glass vessel, with a volume of $50 \mathrm{~cm}^{3}$, was used to carry out the phase equilibrium determinations. The glass vessel was provided with an external jacket in which water at a constant temperature was circulated using a thermostat. The temperature was controlled to within $\pm 0.01$ K. The binodal curves were determined by a titration method. A salt solution of known concentration was titrated with the Brij 58 solution or vice versa, until the solution turned turbid. For determination of the tie lines, feed samples (about $20 \mathrm{~cm}^{3}$ ) were prepared by mixing appropriate amounts of Brij 58, salt, and water in the vessel. The thermostat was set at a desired temperature, and the sample was stirred for 30 min . Then the mixture was allowed to settle for 48 h . After separation of the two phases, the concentration of $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{4}$ and $\mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{4}$ in the top and bottom phases was determined by the phenate method. ${ }^{22}$ The concentration of $\mathrm{KH}_{2} \mathrm{PO}_{4}$ was determined by flame photometry as a spectroscopy method. The concentration of Brij 58 in both phases was determined from refractive index measurements using a refractometer (ABBE 60 model, England) with a precision of $\pm 0.0001$. The relation between the refractive index $n_{\mathrm{D}}$ and the mass fractions of Brij $58\left(w_{1}\right)$ and salt $\left(w_{2}\right)$ is given by

$$
\begin{equation*}
n_{\mathrm{D}}=a_{0}+a_{1} w_{1}+a_{2} w_{2} \tag{1}
\end{equation*}
$$

The values of coefficients $a_{0}, a_{1}$, and $a_{2}$ were listed in Table 1. The precision of the mass fraction of Brij 58 achieved using eq 1 is less than 0.002 . It should be noted that this equation is only valid for dilute solutions of Brij 58 solution and salt, for obtaining the linear calibration plots.

## Results and Discussion

For aqueous systems containing Brij 58 and three salts $\left(\mathrm{KH}_{2} \mathrm{PO}_{4}, \mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{4}\right.$, and $\left.\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{4}\right)$, the binodal and tie

${ }^{a}$ Where $L$ is the number of tie lines and $j=1$ and $2 . \mathrm{SD}_{1}$ and $\mathrm{SD}_{2}$ represent the weight percent standard deviations for Brij 58 and salt, respectively. $\mathrm{SD}_{j}=\left\{1 / 2 L \sum_{j=1}^{L} \sum_{i=1}^{L}\left[\left(100 w_{i, j, \text { calcd }}^{\mathrm{t}}-100 w_{i, j, \text { expt }}^{\mathrm{t}}\right)^{2}+\right.\right.$ $\left.\left.\left(100 w_{i, j, \text { calcd }}^{\mathrm{b}}-100 w_{i, j, \text { expt }}^{\mathrm{b}}\right)^{2}\right]\right\}^{0.5}$.

Superscripts " $t$ " and " $b$ " stand for surfactant-rich phase and saltrich phase, respectively, and subscripts 1,2 , and 3 were denoted for surfactant, salt, and water, respectively. $k_{1}, k_{2}, n$, and $f$ represent fit parameters of eqs 4 and 5 . The data of the three systems also were correlated with two other equations (eqs 6 and 7)

$$
\begin{equation*}
\ln \left(\frac{w_{2}^{\mathrm{t}}}{w_{2}^{\mathrm{b}}}\right)=j+k_{3}^{2}\left(w_{1}^{\mathrm{b}}-w_{1}^{\mathrm{t}}\right) \tag{6}
\end{equation*}
$$

where the $k_{3}$ term is the salting-out coefficient, and $j$ is a constant related to the activity coefficient, respectively. Recently, Zafarani et al. ${ }^{26}$ have used eq 6 to correlate the tie line compositions of systems containing PEG. The last equation has the following expression

$$
\begin{equation*}
w_{2}^{\mathrm{t}}=\left(r+k_{4}^{2}\right) w_{1}^{\mathrm{t}}-\frac{\ln \left(w_{2}^{\mathrm{t}} / w_{3}^{\mathrm{b}}\right)}{k_{4}^{2}} \tag{7}
\end{equation*}
$$

where $k_{4}$ and $r$ represent fit parameters of eq 7. This equation has been used for correlating the tie line data of LLE for polyvinylpyrrolidone in our previous paper. ${ }^{27}$ The fit parameters for eqs 4 to 7 were reported in Table 6.

The standard deviations for eqs 4 to 7 were given in Table 7. From Table 7, we conclude that eq 6 is the best equation to correlate the tie line data for these systems. The comparison of the binodal curves for three systems has been shown in Figure 7. Three salts, $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{4}, \mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{4}$, and $\mathrm{KH}_{2} \mathrm{PO}_{4}$, have been chosen for comparing the cation type on the binodal curves displacement.

As Figure 7 shows, the binodal curves for system 2 (Brij 58 $+\mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{4}+\mathrm{H}_{2} \mathrm{O}$ ) and system 3 (Brij $58+\mathrm{KH}_{2} \mathrm{PO}_{4}+$ $\mathrm{H}_{2} \mathrm{O}$ ) show similar behavior, while system 1 (Brij $58+$ $\left.\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{4}+\mathrm{H}_{2} \mathrm{O}\right)$ presents a very different phase diagram with respect to systems 2 and 3. It means that the cation type

Figure 7. Binodal curves for the Brij $58+$ salt $+\mathrm{H}_{2} \mathrm{O}$ system. $w_{1}$ and $w_{2}$ are mass weight fractions for Brij 58 and salt, respectively, at 298.15 K with salts: $\square,\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{4} ; \mathrm{O}, \mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{4} ; \Delta, \mathrm{KH}_{2} \mathrm{PO}_{4}$.
does not play an important role in the bimodal displacement wherein the main differences between three salts arise from the charge value of the anion. Figure 7shows that increasing the charge of the anion from -1 (for $\mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{4}$ and $\mathrm{KH}_{2} \mathrm{PO}_{4}$ ) to -2 (for $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{4}$ ) will cause a decrease of the salt concentration.

Ananthapadmanabhan et al. ${ }^{28}$ have observed a similar trend in the case of aqueous PEG-salt systems with three salts, NaOH , $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and $\mathrm{Na}_{3} \mathrm{PO}_{4}$. The effectiveness of the anion in forming an aqueous two-phase system with PEG was found to be $\mathrm{PO}_{4}{ }^{-3}$ $>\mathrm{SO}_{4}^{-2}>\mathrm{OH}^{-}$. They postulated that anions with a higher valence are better salting-out agents than anions with a lower valence because the higher valence anion hydrates more water than the lower valence anion, thus decreasing the amount of water available to hydrate PEG. This trend has theoretically been predicted by Kenkare. ${ }^{29}$

In addition to mentioned salts, two other salts, i.e., NaCl and $\mathrm{K}_{2} \mathrm{HPO}_{4}$, were examined to obtain a proper ATPS, but none of them were suitable ATPSs. The aqueous system containing Brij 58 and NaCl did not have an obvious turbid point for determination of the bimodal diagram, and also salt $\mathrm{K}_{2} \mathrm{HPO}_{4}$ was hardly solved in Brij 58 solution and caused error in the bimodal diagram determination.

## Conclusions

For three aqueous solution systems containing surfactant Brij 58 with three salts $\left(\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{4}, \mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{4}\right.$, and $\mathrm{KH}_{2} \mathrm{PO}_{4}$ ), the binodal and tie line data were determined at 298.15 K. The binodal and tie line data for these systems were satisfactorily described by proposed equations. There is mainly a difference between phase diagrams of systems containing $\mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{4}$ and $\mathrm{KH}_{2} \mathrm{PO}_{4}$ and the phase diagram of the system containing $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{4}$. It seems that the charge of the anion plays an important role in the displacement of the phase diagram.

Our experimental data for ATPSs containing surfactant Brij 58 with three salts demonstrate that surfactant Brij 58 can be a proper candidate for ATPSs as well as polyethylene glycol and polyvinylpyrrolidone, and it can be considered as a suitable case for separation of biological materials such as membrane proteins.
