Vapor–Liquid Equilibria of Binary Systems Comprising 1-Chloro-2-ethylhexane and 2-Ethyl-1-hexanol

Elena Gracová and Pavol Steltenpohl*

Department of Chemical and Environmental Engineering, Faculty of Chemical and Food Technology, Slovak University of Technology, 812 37 Bratislava, Slovak Republic

Vapor–liquid equilibria of four binary systems comprising *N,N*-dimethylformamide or toluene + 1-chloro-2-ethylhexane or + 2-ethyl-1-hexanol were measured at a pressure of 79.99 kPa. The corresponding sets of binary equilibrium data were fitted using the NRTL, Redlich–Kister, UNIQUAC, and Wilson models. Binary parameters of the chosen excess molar Gibbs energy models were calculated on the basis of the maximum likelihood procedure assuming ideal behavior of the vapor phase. Consistency of the measured data sets was tested showing good to excellent quality of experimental data.

Introduction

2-Ethyl-1-hexanol is a fatty alcohol used in the production of esters. Besides its principal use, production of bis(2-ethylhexyl) phthalate, other esters of this alcohol find application in the pharmaceutical industry and cosmetics, due to their emollient properties. Similarly, 1-chloro-2-ethylhexane is used in cosmetics as a UV-adsorbing component.

This study is intended to supply basic data necessary for simulation of separation of these compounds from mixtures containing industrial solvents. For this purpose, vapor–liquid (V–L) equilibria of *N,N*-dimethylformamide and toluene with 1-chloro-2-ethylhexane and 2-ethyl-1-hexanol were measured at a pressure of 79.99 kPa. To our knowledge, V–L equilibrium data of the chosen binary mixtures are absent in the literature.

Experimental

2-Ethyl-1-hexanol of chromatographic purity (99.6 %) was purchased from Aldrich. 1-Chloro-2-ethylhexane was supplied by CIBA Spezialitätenchemie AG. Its purity estimated by gas chromatography was 96.3 %. *N,N*-Dimethylformamide was obtained from Riedel de Haën and was guaranteed at 99.9 % purity. Toluene (analytical grade, Lachema Neratovice, Czech Republic) was redistilled at atmospheric pressure using a column with 20 theoretical plates. Its chromatographic purity was 99.6 %. All chemicals were stored over molecular sieves to avoid a possible contamination with atmospheric moisture. The properties of compounds are listed in Table 1.

Isobaric vapor–liquid equilibrium data sets for four binary systems, *N,N*-dimethylformamide + 1-chloro-2-ethylhexane, *N,N*-dimethylformamide + 2-ethyl-1-hexanol, toluene + 1-chloro-2-ethylhexane, and toluene + 2-ethyl-1-hexanol, were obtained by the circulation method in a modified Gillespie still described elsewhere.⁵ Temperature was measured within an uncertainty of ± 0.05 K by a resistance thermometer. The pressure inside the measuring still was kept constant with an uncertainty of ± 13 Pa. The analyses of

the liquid and vapor phase compositions were carried out chromatographically with an uncertainty of the component mole fractions ± 0.5 % and better.

The sets of *t*, *x*, *y* equilibrium data obtained for the four binary systems are given in Tables 2 and 3.

Results and Discussion

V–L equilibrium data of the studied binary systems were correlated using the NRTL, Redlich–Kister, UNIQUAC, and Wilson equations. In all cases, the model parameters were calculated using the maximum likelihood principle.⁶ The objective function used adopted the form

$$F = \sum_n \left[(x_1 - x_{\text{calc},1})^2 + (y_1 - y_{\text{calc},1})^2 + \left(\frac{P - P_{\text{calc}}}{P} \right)^2 \right] \quad (1)$$

where (y_1 and $y_{\text{calc},1}$) and (x_1 and $x_{\text{calc},1}$) represent measured and calculated mole fractions of component 1 in the vapor and liquid phase, respectively. The objective function (eq 1) was minimized in two independent iteration cycles.⁷ By this procedure, the optimum parameters of the excess molar Gibbs energy equations and independent variables $x_{\text{calc},1}$ were obtained.

Mole fraction of component 1 in the vapor phase, $y_{\text{calc},1}$, and total pressure P_{calc} were calculated using the following relationships

$$y_{\text{calc},1} = \frac{x_{\text{calc},1} \gamma_1 P_1^*}{(x_{\text{calc},1} \gamma_1 P_1^* + x_{\text{calc},2} \gamma_2 P_2^*)} \quad (2)$$

$$P_{\text{calc}} = \gamma_1 x_1 P_1^* + \gamma_2 x_2 P_2^* \quad (3)$$

where γ_i represents the value of the *i*th component activity coefficient. Saturated vapor pressures P^* of pure components at experimental temperatures were computed by the Antoine equation (Table 1).

Calculated values of the G^E parameters for the NRTL, Redlich–Kister, UNIQUAC, and Wilson equations are given in Table 4. For the NRTL model also the values of mean deviations in mole fractions of the liquid and vapor phases (d_x , d_y) and those of mean deviations in temperature (d_t) are

G^E models. Table 5 summarizes the composition and temperature data of the azeotrope observed in the mixture of *N,N*-dimethylformamide + 1-chloro-2-ethylhexane calculated employing the above-mentioned model equations. The fit (by the NRTL equation) of experimental equilibrium data for the chosen systems at the pressure of 79.99 kPa is presented in Figures 1 to 4.

Consistency of the experimental data sets was tested according to Herington⁸ (Redlich and Kister⁹). The results obtained employing the NRTL model equation are presented in Figure 5 and show that the sets of measured VLE data fulfill the requirements of the area test. Furthermore, the direct test of thermodynamic consistency¹⁰ for the four studied binary systems was carried out. The proposed measure of the experimental data consistency corresponds to the residue mean square (rms) value of $\delta \ln(\gamma_1/\gamma_2)$, i.e., the differences between the logarithms of the activity coefficient ratio calculated by the model equation and directly from the experimental data. The worst consistency was observed in the case of the binary system *N,N*-dimethylformamide + 1-chloro-2-ethylhexane with the rms value of 0.137. According to Van Ness,¹⁰ the respective consistency index (CI) of the experimental data set is equal to 6, i.e., medium

quality data. However, Figure 6 shows that the first two experimental points of this data set are seriously deviated. Omitting these two points, the consistency index would drop to $CI = 2$ ($rms = 0.028$), which is very good to excellent consistency. Relatively good consistency was attributed to the binary system toluene + 2-ethyl-1-hexanol ($rms = 0.087$, $CI = 4$), while for the systems *N,N*-dimethylformamide + 2-ethyl-1-hexanol and toluene + 1-chloro-2-ethylhexane, the consistency

was excellent with rms values of 0.026 ($CI = 2$) and 0.019 ($CI = 1$), respectively.

Conclusions

Sets of experimental VLE data were obtained for the binary systems composed of *N,N*-dimethylformamide/toluene with

1-chloro-2-ethylhexane/2-ethyl-1-hexanol. Formation of a minimum boiling temperature azeotrope was observed in the case of the *N,N*-dimethylformamide + 1-chloro-2-ethylhexane binary system. Consistency of experimental data was proved on the basis of the area test as well as the direct test of thermodynamic consistency. According to the later test, while omitting the most deviated points, the quality of measured data was classified from good to excellent.
