ABSTRACT: The ionic interactions have been investigated from the isopiestic measurements on the quaternary systems $\text{H}_2\text{O}-\text{Er}(\text{NO}_3)_3-\text{La}(\text{NO}_3)_3-\text{Pr}(\text{NO}_3)_3$, $\text{H}_2\text{O}-\text{Er}(\text{NO}_3)_3-\text{La}(\text{NO}_3)_3-\text{Nd}(\text{NO}_3)_3$, and $\text{H}_2\text{O}-\text{Er}(\text{NO}_3)_3-\text{Pr}(\text{NO}_3)_3-\text{Nd}(\text{NO}_3)_3$ at 298.15 K to near saturation. The isopiestic measurements can be represented by a modified Pitzer ion-interaction model extending to $C^{(3)}$ within the experimental uncertainty over a full concentration range. In addition, the Zdanovskii–Stokes–Robinson model or partial ideal solution model is obeyed by all of the systems within isopiestic accuracy, indicating zero exchange energy between the unlike salts, which is consistent with the nature of rare earth elements.

INTRODUCTION

The Pitzer ion-interaction model,^{1–3} which contains a Debye–Hückel limiting law parameter and the empirically determined $\beta^{(0)}$, $\beta^{(1)}$, and C^ϕ parameters, has widely been used in the representation of thermodynamic properties of aqueous electrolyte solutions and their mixtures to moderate ionic strengths. Recently, various modifications to the Pitzer ion-interaction model extending either to $\beta^{(2)}$, $C^{(2)}$, or $D^{(2)}$ have been introduced for highly soluble 1–1, 2–1, and 2–2 electrolytes^{4–7} and their mixtures.^{8,9} However, all of them cannot fit the highly soluble and highly unsymmetrical electrolytes very well, particularly for rare earth nitrates, chlorides, and perchlorates, where their standard deviations are significantly higher than the experimental errors of the precise isopiestic measurements of Spedding et al.¹⁰ and Rard et al.^{11–17} We¹⁸ found this problem could simply be solved by introducing a $C^{(3)}$ parameter into the Pitzer ion-interaction model, which can quantitatively represent these literature isopiestic^{10–17} measurements up to the maximum saturate or supersaturate concentrations available.

Ionic interactions in the 3–1 actinide and lanthanide ions may follow a similar ion-interaction trend due to the similarity of actinides and lanthanides, but the actinides can hardly be manipulated at high concentrations due to their radioactivity. Therefore, thermodynamic properties from infinite dilution to saturation (or supersaturation) are of fundamental importance for the pure and mixed aqueous solutions containing 3–1 rare earth electrolytes.

On the other hand, based on the Zdanovskii–Stokes–Robinson (ZSR) model^{19–23} for aqueous solutions, we have developed a partial ideal solution model^{24–29} for every kind

of the multicomponent systems A–B–C–...–Z with zero interchange energies among B, C, ..., Z related to their binary subsystems A–B, A–C, ..., A–Z at constant activity of the common component A. The partial ideal solution model has been verified by the experiments of organic mixtures, aqueous and nonaqueous solutions, alloys, molten salt mixtures, slags, and nonstoichiometric solid solutions. However, for aqueous electrolyte mixtures, the model testing is normally available only to moderate ionic strengths. It is therefore interesting to examine whether the new isopiestic measurements for quaternary mixed rare earth electrolyte solutions to very high concentrations still follow the ZSR model (or the partial ideal solution model).

In this paper, we tried to extend the isopiestic measurements to the quaternary systems $\text{H}_2\text{O}-\text{Er}(\text{NO}_3)_3-\text{La}(\text{NO}_3)_3-\text{Pr}(\text{NO}_3)_3$, $\text{H}_2\text{O}-\text{Er}(\text{NO}_3)_3-\text{La}(\text{NO}_3)_3-\text{Nd}(\text{NO}_3)_3$, and $\text{H}_2\text{O}-\text{Er}(\text{NO}_3)_3-\text{Pr}(\text{NO}_3)_3-\text{Nd}(\text{NO}_3)_3$ to near saturation and to represent the new measurements by the new simple modified ion-interaction model, the ZSR or partial ideal solution model, and other empirical equations.

EQUATIONS

For highly soluble and highly unsymmetrical electrolytes (MX) such as aqueous rare earth nitrates, perchlorates, and chlorides and their mixtures (MX–NX–...) with the same

^aGiven in mol·kg^{–1}.

i denotes all ions, z is the charge number, ν is the stoichiometric coefficient, m is molality, and m_T is the total solute molality, and B and C are virial terms for pairwise and triplet interactions of the like salts given by

$$B_{cX} = \beta_{cX}^{(0)} + \beta_{cX}^{(1)}g(\alpha_{B1}I^{1/2}) + \beta_{cX}^{(2)}g(\alpha_{B2}I^{1/2}) \quad (3a)$$

$$C_{cX} = C_{cX}^{\phi}/2|z_c z_X|^{1/2} \quad (3b)$$

$$B_{cX}^{\phi} = \beta_{cX}^{(0)} + \beta_{cX}^{(1)} \exp(-\alpha_{B1}I^{1/2}) + \beta_{cX}^{(2)} \exp(-\alpha_{B2}I^{1/2}) \quad (3c)$$

$$C_{cX}^{\phi} = 2[C_{cX}^{(0)} + C_{cX}^{(1)} \exp(-\alpha_{C1}I) + C_{cX}^{(2)} \exp(-\alpha_{C2}I) + C_{cX}^{(3)} \exp(-\alpha_{C3}I)] \quad (3d)$$

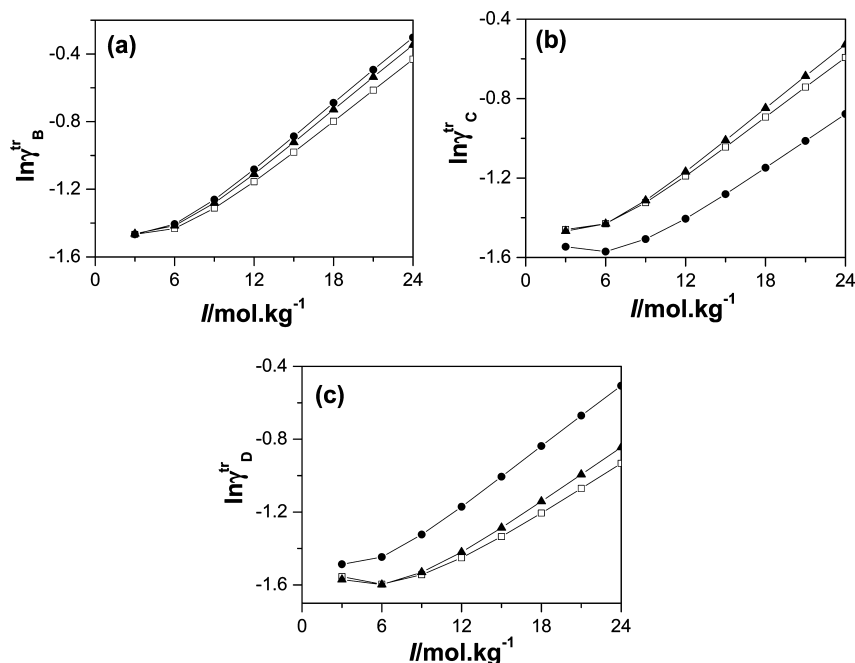

Figure 1. Dependence of (a) $\ln \gamma_B^{\text{tr}}$ on I , (b) $\ln \gamma_C^{\text{tr}}$ on I , and (c) $\ln \gamma_D^{\text{tr}}$ on I for the quaternary systems \square , $\text{H}_2\text{O}-\text{Er}(\text{NO}_3)_3(\text{B})-\text{La}(\text{NO}_3)_3(\text{C})-\text{Pr}(\text{NO}_3)_3(\text{D})$; \bullet , $\text{H}_2\text{O}-\text{Er}(\text{NO}_3)_3(\text{B})-\text{La}(\text{NO}_3)_3(\text{C})-\text{Nd}(\text{NO}_3)_3(\text{D})$; and \blacktriangle , $\text{H}_2\text{O}-\text{Er}(\text{NO}_3)_3(\text{B})-\text{Pr}(\text{NO}_3)_3(\text{C})-\text{Nd}(\text{NO}_3)_3(\text{D})$.

$$C_{cX}^{\gamma} = 3C_{cX}^{(0)} + C_{cX}^{(1)}[g(\alpha_{C1}I) + 2 \exp(-\alpha_{C1}I)] \\ + C_{cX}^{(2)}[g(\alpha_{C2}I) + 2 \exp(-\alpha_{C2}I)] \\ + C_{cX}^{(3)}[g(\alpha_{C3}I) + 2 \exp(-\alpha_{C3}I)] \quad (3e)$$

where $g(x) = 2\{1 - [(1+x)\exp(-x)/x^2]\}$ and θ and ψ are mixing terms for pairwise and triplet interactions of the unlike salts.

On the other hand, the modified ZSR equation at constant water activity and the McKay–Perring equation for aqueous mixtures may be given respectively by^{21–23,30}

$$\Delta = \sum_j (m_j/m_j^{\circ}) - 1 \quad (4)$$

$$\nu_j \ln(m_T \gamma_j / m_j^{\circ} \gamma_j^{\circ}) = \int_0^{\ln a_w} \{ \partial[\Delta/m_T(1-y_j)] / \partial [1/(1-y_j)] \} d \ln a_w \quad (5)$$

and the Harned equation³¹ at constant total ionic strength, which is often used for the aqueous electrolyte mixtures to moderate ionic strengths,^{31–34} may be given by

$$\ln \gamma_j = \ln \gamma_j^{\circ} - \sum_k \alpha_{jk} y_k - \sum_k \beta_{jk} y_k^2 \\ - \sum_k \sum_l \beta_{jkl} y_k y_l \quad (6)$$

where $y_j = m_j/m_T$, $y_l = m_l/m_T$, j , k , and l denote different electrolytes, the superscript $^{\circ}$ denotes the quantity of aqueous pure electrolytes, and α and β are the Harned coefficients. In one special case of $\Delta = 0$, eq 4 reduces to the ZSR model

$$\sum_j (m_j/m_j^{\circ}) = 1 \quad (7)$$

and, if eq 7 holds from $a_w = 1$ to $a_w = a_w$, eq 5 reduces to the simplified McKay–Perring equation

$$m_T \gamma_j / m_j^{\circ} \gamma_j^{\circ} = 1 \quad (8)$$

In another special case of all $\beta = 0$, eq 6 reduces to the Harned rule³¹

$$\ln \gamma_j = \ln \gamma_j^{\circ} - \sum_k \alpha_{jk} y_k \quad (9)$$

EXPERIMENTAL SECTION

Er_2O_3 , La_2O_3 , Pr_6O_{11} , and Nd_2O_3 (99.99 % from Aldrich Chemical Co.) were used to prepare stock solutions of $\text{Er}(\text{NO}_3)_3$, $\text{La}(\text{NO}_3)_3$, $\text{Pr}(\text{NO}_3)_3$, and $\text{Nd}(\text{NO}_3)_3$ by Rard's method.^{11–17} After reacting the rare earth oxides with the analytical reagent HNO_3 , the resulting rare earth nitrate solutions were adjusted to equivalent concentrations with dilute HNO_3 solutions and then reheated and readjusted until stabilized. The rare earth nitrate molalities were determined by the ethylenediaminetetraacetic acid (EDTA) titration and by the gravimetric sulfate method, after destroying the nitrate ions by evaporation with hydrochloric acid. The stock solution concentrations were known to be 0.1 % or better. NaCl and CaCl_2 from the same source were recrystallized from water several times and dried over P_2O_5 . The concentrations of aqueous NaCl and CaCl_2 were determined by the AgNO_3 titration. All of the solutions were prepared by weight in triple-distilled water and converted into mass. The aqueous NaCl and CaCl_2 were used as isopiestic standards for the dilute and concentrated rare earth nitrate solutions, respectively, and their osmotic coefficients were taken from the recent literature sources.^{35,36} At isopiestic equilibrium, all samples have the same water activity, so that the osmotic coefficients of the rare earth nitrate solutions may

be calculated by the equation

$$\phi = \nu^* m^* \phi^* / \sum_j \nu_j m_j \quad (10)$$

from the known properties of isopiestic reference solutions NaCl or CaCl₂ denoted by the asterisk.

The isopiestic measurements were made by the method described previously.^{37–42} Fourteen gold-plated silver cups were placed in an isopiestic apparatus made of copper. Each sample was run in duplicate. In each of the cups, one glass ball and (1.5 to 3.0) g of reference solution or investigated system were placed. After evacuating air, the apparatus was rocked once every 5 s in the thermostat controlled at 298.15 ± 0.01 K during the whole experimental process. The isopiestic measurements were carried out from $I \approx 6 \text{ mol}\cdot\text{kg}^{-1}$ to $I \approx 24 \text{ mol}\cdot\text{kg}^{-1}$ (i.e., near to saturation) for the investigated systems. The isopiestic equilibrium may be reached within (5 to 7) days.

After each run, the isopiestic molalities were determined by weighing only as usual.^{37–42} The individual equilibrium molalities of each nitrate were always reproducible to ± 0.06 % and mostly to ± 0.04 % between the duplicate samples.

RESULTS AND DISCUSSION

First, we discuss the solute–solute interchange energies in the quaternary mixed rare earth electrolyte solutions. Table 1 lists the isopiestic results for the quaternary systems H₂O–Er(NO₃)₃–La(NO₃)₃–Pr(NO₃)₃, H₂O–Er(NO₃)₃–La(NO₃)₃–Nd(NO₃)₃, and H₂O–Er(NO₃)₃–Pr(NO₃)₃–Nd(NO₃)₃ at 298.15 K, where ϕ_{exp} was determined by eq 10. The isopiestic molalities of these systems are compared with the ZSR or partial ideal solution model. The results show that the Δ function defined by eq 4 is given by $|\Delta| \leq 0.001$ for all of the systems over the entire concentration range, which is within the isopiestic experimental accuracy.⁴³ This means that all of the systems obey the ZSR or partial ideal solution model within experimental error. It has been earlier noted that the physical meaning of the ZSR or partial ideal solution model is zero interchange energy between the unlike solutes in the mixtures. This behavior is consistent with the nature of the rare earth mixtures. Thus, the solute activity coefficients of the mixtures may be calculated very easily from the data of pure electrolytes by eq 8.

Second, we discuss the ionic interactions in the quaternary mixed rare earth electrolyte solutions based on the new simple modified Pitzer model, eqs 1 to 3. Table 2 lists seven parameters ($\beta^{(0)}$, $\beta^{(1)}$, $\beta^{(2)}$, $C^{(0)}$, $C^{(1)}$, $C^{(2)}$, and $C^{(3)}$) for each pure salt which were first reported in ref 18. Table 3 gives two mixing parameters ($\theta_{cc'}$ and $\psi_{cc'X}$) for each pair of salts, among which data of the last three mixtures were first reported in ref 18. Table 3 shows the much smaller mixing parameter values of the La(NO₃)₃–Pr(NO₃)₃, La(NO₃)₃–Nd(NO₃)₃, and Pr(NO₃)₃–Nd(NO₃)₃ mixtures than the Er(NO₃)₃–La(NO₃)₃, Er(NO₃)₃–Pr(NO₃)₃, and Er(NO₃)₃–Nd(NO₃)₃ mixtures and the very small increase, 0.0002, in root-mean-square average values when omitting the mixing terms for La(NO₃)₃–Pr(NO₃)₃, La(NO₃)₃–Nd(NO₃)₃, and Pr(NO₃)₃–Nd(NO₃)₃. Therefore, two mixing parameters ($\theta_{cc'}$ and $\psi_{cc'X}$) for La(NO₃)₃–Pr(NO₃)₃, La(NO₃)₃–Nd(NO₃)₃, and Pr(NO₃)₃–Nd(NO₃)₃ mixtures can be omitted. The osmotic coefficients calculated by eq 1, ϕ_{calc} are listed in the seventh column of Table 1. The values of $\Delta\phi$ ($\equiv \phi_{\text{exp}} - \phi_{\text{calc}}$) are listed in the eighth column of Table 1. The values of $|\Delta\phi| \leq 0.002$ indicate

that the simple modification to the Pitzer ion-interaction model extending to the $C^{(3)}$ parameter can represent the new measurements within experimental uncertainty over the full concentration range. Thus, the solute activity coefficients of all of the mixtures may also be calculated from the parameters listed in Tables 2 and 3 by eq 2.

The calculated values of trace activity coefficient, $\ln \gamma_j^{\text{tr}}$, are generally sensitive to the method of representing experimental ϕ_{exp} data.¹⁶ It is therefore interesting to compare the $\ln \gamma_j^{\text{tr}}$ values of the rare earth nitrate mixtures calculated from the new simple modified ion-interaction model, eq 2, and from the simplified McKay–Perring equation, eq 8. Both of them show excellent agreement at lower ionic strengths but present some differences at higher ionic strengths. The largest differences in the $\ln \gamma_j^{\text{tr}}$ values from the two calculation approaches are $\sigma_{\text{max}} \leq 0.020$ at $I = 9 \text{ mol}\cdot\text{kg}^{-1}$ and to $\sigma_{\text{max}} = 0.042$ to 0.055 at $I = 24 \text{ mol}\cdot\text{kg}^{-1}$ for the H₂O–Er(NO₃)₃–La(NO₃)₃–Pr(NO₃)₃, H₂O–Er(NO₃)₃–La(NO₃)₃–Nd(NO₃)₃, and H₂O–Er(NO₃)₃–Pr(NO₃)₃–Nd(NO₃)₃ systems. Figure 1 presents the similar ionic strength dependence trend of $\ln \gamma_B^{\text{tr}}$, $\ln \gamma_C^{\text{tr}}$, and $\ln \gamma_D^{\text{tr}}$ for the three quaternary systems. The plots show the regular increase in trace activity coefficients with increasing ionic strength at $I \geq 6 \text{ mol}\cdot\text{kg}^{-1}$.

We also compared the solute activity coefficients of the quaternary systems H₂O–Er(NO₃)₃–La(NO₃)₃–Pr(NO₃)₃, H₂O–Er(NO₃)₃–La(NO₃)₃–Nd(NO₃)₃, and H₂O–Er(NO₃)₃–Pr(NO₃)₃–Nd(NO₃)₃ at $I = (3, 6, 9, 12, 15, 18, 21, \text{ and } 24) \text{ mol}\cdot\text{kg}^{-1}$ with the Harned rule, eq 9. The maximum deviation obtained at high ionic strengths is $\sigma_{\text{max}} = 0.0043$. Therefore, the solute activity coefficients of the quaternary systems H₂O–Er(NO₃)₃–La(NO₃)₃–Pr(NO₃)₃, H₂O–Er(NO₃)₃–La(NO₃)₃–Nd(NO₃)₃, and H₂O–Er(NO₃)₃–Pr(NO₃)₃–Nd(NO₃)₃ were refitted by the Harned equation, eq 6. Table 4 lists the Harned coefficients (α_{jk} , α_{jk} , β_{jk} , β_{jk} , and β_{jkl}) of the three quaternary systems with the fitting standard deviation $\sigma \leq 0.001$.

CONCLUSION

In this study, we have reported experimental isopiestic osmotic coefficient measurements on the quaternary systems H₂O–Er(NO₃)₃–La(NO₃)₃–Pr(NO₃)₃, H₂O–Er(NO₃)₃–La(NO₃)₃–Nd(NO₃)₃, and H₂O–Er(NO₃)₃–Pr(NO₃)₃–Nd(NO₃)₃ at 298.15 K to near saturation. The new modified Pitzer ion-interaction model only extending to the $C^{(3)}$ parameter and the ZSR or partial ideal solution model are used to represent the experimental results. The agreement is excellent among the isopiestic measurements, the new simple modified Pitzer model, and the ZSR or partial ideal solution model. The calculated solute activity coefficients for the quaternary systems also show the consistence among the new simple modified Pitzer model, the McKay–Perring equation, and the Harned equation. All of the interaction analysis suggests the applicability of the new simple modified Pitzer model and the ZSR or partial ideal solution model for the rare earth electrolyte mixtures up to very high concentrations.
