Abstract. Homopolymerization of methyl methacrylate (MMA) was carried out in the presence of triphenylstibonium 1,2,3,4-tetraphenyl-cyclopentadienylide as an initiator in dioxane at $65^{\circ}C \pm 0.1^{\circ}C$. The system follows non-ideal radical kinetics ($R_p \propto [M]^{1.4} [I]^{0.44}$) due to primary radical termination as well as degradative chain-transfer reaction. The overall activation energy and average value of k_p^2/k_t were 64 kJ mol⁻¹ and $0.173 \times 10^{-3} 1 \text{ mol}^{-1} \text{ s}^{-1}$ respectively.

Keywords. Triphenylstiboniumylide; methyl methacrylate; non-ideal radical kinetics; mechanism.

1. Introduction

The stereospecific polymerization of various acrylates and methacrylate has been studied by using a variety of initiators such as triphenyl phosphine and iron(III) complex,¹ thiol,² the D-glucose-ceric ion redox system,³ benzyol peroxide,⁴ tert-hexyl peroxy pivalate⁵ and fullerene.⁶ Recently, some ylides containing non-metals like nitrogen,⁷⁻¹⁰ sulphur¹¹ and phosphorus¹² have been used for the polymerization of methyl methacrylate MMA.

Recently use of *p*-acetylenzylidene triphenyl arsonium ylide [*p*-ABTAY] as radical initiator for the homopolymerization of methyl methacrylate,¹³ vinyl acetate¹⁴ and copolymerization of styrene with vinyl acetate¹⁵ has been reported.

The properties of ylides are very much dependent on the identity of the heteroatom. The dipolar and nucleophilic character of the ylides appear to increase their stability. However, the triphenylstibonium 1,2,3,4-tetraphenylcyclopentadienylide, because of its synthetic problems, has not been examined earlier in the polymer science.

2. Experimental

Monomer and solvents were purified according to procedures reported in literature.^{16,17} The ylide was prepared by the method of Lloyd.¹⁸ Briefly it is as follows. A solution of $2 \cdot 19 \times 10^{-4}$ moles of 1,2,3,4-tetraphenylcyclopentadiene (Aldrich), $7 \cdot 46 \times 10^{-4}$ moles of *p*-toluene sulphonylhydrazide (Fluka AG) in $6 \cdot 3$ ml diethyl amine was kept at 0°C for 10 days. It was then followed by addition of $3 \cdot 5$ ml water, 5 ml ether and dried over anhydrous silica gel, when yellow crystals of diazo compound were obtained. It was washed with methanol.

A solution containing 2.64×10^{-4} moles of diazocompound, 7.35×10^{-5} moles of Cu(II) bishexafluoroacetylacetonato (Merck) as catalyst and 4.95×10^{-5} moles of triphenylstibonium (Merck) in 10 ml benzene were refluxed for 2 h. The evaporation of the solvent in vacuum produced stibonium ylide in 14.5% yield.

3. Polymerization procedure

The polymerization was carried out in a dioxane at $65 \pm 0.1^{\circ}$ C under an inert atmosphere of nitrogen for 5 h. The rate of polymerization (R_p) was determined dilatometry from the slope of linear portion of conversion vs time plots. The intrinsic viscosity [**h**] of polymer(s) was determined in benzene at $30 \pm 0.1^{\circ}$ C using an ubbelohde viscometer. The average degree of polymerization (\bar{P}_n) was calculated.¹⁹

4. Results and discussion

The ylide initiated polymerization at 65° C have been summarized in (tables 1–3) and (figures 1–8)

^{*}For correspondence

because it failed to initiate the polymerization below 60° C.

4.1 *Effect of [ylide]*

The effect of stibonium ylide on the rate of polymerization was studied by varying the [ylide] from 1.16×10^{-5} to 5.78×10^{-5} mol Γ^1 , while keeping [MMA] constant as $3.0 \text{ mol }\Gamma^1$ (figure 1 and table 1). The polymerization was associated with an induction period of about 50-60 min. The extended induction period is often seen feature in the case of vlide initiated polymerization of various vinyl monomers.²⁰ The ylide initiated the radical polymerization of methyl methacrylate and the R_p increased when ylide concentration increased from 1.16×10^{-5} to 5.78×10^{-5} mol Γ^1 . The value is less than expected for ideal radical kinetics. The initiator exponent, calculated from the slope of the plot $\log R_p$ versus log [ylide], is 0.44 ± 0.01 (Figure 2). The average degree of polymerization (\overline{P}_n) decreases with the increase in [ylide] (table 1). The value of k_p^2/k_t , determined from the slope of a plot (figure 3) of $(1/\bar{P}_n)$ vs $R_p/[M]^2$, is $0.173 \times 10^{-3} 1 \text{ mol}^{-1} \text{ s}^{-1}$.

4.2 Effect of [MMA]

The effect of [MMA] on the R_p has been studied by varying [MMA] from 0.75 to 3.0 mol Γ^1 , whereas [ylide] has been kept constant 2.31×10^{-5} mol Γ^1 (table 2). It is clear that the R_p is a direct function of [MMA]. The monomer exponent, calculated from the slope of the linear plot of log R_p against log [MMA], is 1.4 ± 0.02 (figure 4). This confirms that the system follows non-ideal kinetics. The average degree of polymerization increases with increase of monomer concentration (table 2).^{21–22}

plot of $\log R_p$ vs polymerization temperature, is 64 kJ mol⁻¹ (figure 5).

4.4 *Causes of non-ideality*

The value of initiator exponent suggests that the system follows non-ideal kinetics. The kinetic non-ideality can be explained by analyzing the role of triphenyl stibonium 1,2,3,4-tetraphenyl-cyclopen-diene as primary radical termination and degradative chain transfer agent. To analyze the effect of primary

Figure 3. Relationship between $1/\overline{P}_n$ and $R_p/[M]^2$ for the homopolymerzation of methyl methacrylate: [ylide] = 1.16 to 5.78×10^{-5} mol Γ^{-1} ; [MMA] = 3.0 mol Γ^{-1} ; temp. = $65 \pm 0.1^{\circ}$ C; time = 300 min; solvent = dioxene.

Figure 4. Relationship log [MMA] and log R_p for the homopolymerzation of methyl methacrylate: [ylide] = $2 \cdot 31 \times 10^{-5} \text{ mol } \Gamma^{-1}$; [MMA] = $0 \cdot 75$ to $3 \cdot 0 \text{ mol } \Gamma^{-1}$; temp. = $65 \pm 0.1^{\circ}$ C; time = 300 min; solvent = dioxene.

radical termination a suitable modified expression given by Deb and Meherhoff²³ in the following form is used:

Figure 5. Plot of $\log R_p$ vs polymerization temperature (Arrhenius plot): [ylide] = $2 \cdot 31 \times 10^{-5}$ mol Γ^{-1} ; [MMA] = $3 \cdot 0$ mol Γ^{-1} ; temp. = 65, 70, $75 \pm 0 \cdot 1^{\circ}$ C; time = 300 min; solvent = dioxene.

Figure 6. Plot of $\log R_p^2/[Y][M]^2$ and $R_p/[M]^2$: [ylide] = 1.16 to $5.78 \times 10^{-5} \text{ mol } \Gamma^1$; [MMA] = 2.53 mol Γ^1 ; temp. = $65 \pm 0.1^{\circ}$ C; time = 300 min; solvent = dioxene.

Figure 7. Plot of $\log R_p^2/[Y][M]^2$ and [Y]/[M]: [ylide] = 1.16 to $5.78 \times 10^{-5} \text{ mol } \Gamma^1$; [MMA] = 2.53 mol Γ^1 ; temp. = $65 \pm 0.1^{\circ}$ C; time = 300 min; solvent = dioxene.

$$\log \frac{R_p^2}{[Y][M]^2}$$
$$= \log \frac{2f_k k_d k_p^2}{k_t} - 0.8684 \frac{k_{prt}}{k_y \times k_p} \times \frac{R_p}{[M]^2}$$

where *Y* and *M* represent ylide and monomer respectively. A plot of the above equation vs $R_p/[M]^2$ gave a negative slope (figure 6) indicating primary radical termination due to ylide for the present system. The following equation, derived by Deb²⁴ and further simplified by Ghosh and Mitra²⁵ was used to examine the role of ylide as degradative chain transfer agent:

$$\log \frac{R_p^2}{[Y][M]^2} = \frac{\log 2f_k k_d k_p^2}{k_t} - 0.434 \frac{k_p^2}{k_t} \times \frac{k_{rt} Y}{k_{il} k_p} \times C_1 \frac{[Y]}{[M]}$$

where C_1 is the ylide transfer constant. The plot of the above equation vs [Y]/[M] also gave a negative slope (figure 7), thereby suggesting chain transfer reaction due to ylide.

The non-ideal kinetics in the arsonium ylide initiated polymerization of vinyl monomers like vinyl acetate¹⁴ MMA^{13,26} has been attributed to primary

Figure 8. ESR spectrum of polymethyl methacrylate mixture.

5. Mechanism

The effect of free radical inhibitors like hydroquinone, aniline and nitrobenzene on the polymerizaiton under the same reaction conditions (table 3) has also been studied to conform free radical mode of polymerization. Triphenylstibonium 1,2,3,4-tetraphenylcyclopentadienylide undergoes bond fission between the heteroatom and the phenyl group to yield phenyl radical²⁹ which initiates polymerization reaction. This is confirmed by ESR spectrum (the ESR spectrum was recorded on X-band EPR 109 Eline century series spectrometer at room temperature) of living system at 2 h which show six hyperfine lines due to the phenyl radical (figure 8).

5.1 *Generation of initiator radical*

The initiation step is as follows:

$$C_{6}H_{5} + CH_{2} = C - COOCH_{3} \longrightarrow C_{6}H_{5} - CH_{2} - \dot{C} - COOCH_{3}$$

 $CH_{3} \qquad CH_{3} = CH_{2} - \dot{C} - COOCH_{3}$

6. Conclusions

On the basis of the above evidences it may be concluded that the polymerization of methyl methcrylate initiated by triphenyl stibonium 1,2,3,4-tetraphenycyclopentadienylide, follows non-ideal radical kinetics due to primary radical termination as well as degradative chain transfer reaction.
