## Abstract

A simple and efficient method for multiple determination of 77 pesticides, including one organonitrogen, eight carbamate, 12 pyrethroid, 26 organochloride, 30 organophosphorous compounds, in textiles is developed. Six representative textiles are chosen as test samples. Extraction using hexane–ethyl acetate (1:1) assisted by ultrasonic processor is carried out twice, followed by clean-up using solid-phase extraction on a florisil column. The final solution is analyzed using gas chromatography–mass spectrometry, and 77 pesticides are determined. This method is highly sensitive, selective, and reproducible, with a broad linear range and reliable accuracy. Six blank samples are spiked with 0.50 and 2.00 mg/kg of the 77 pesticides, and the corresponding recoveries are between 64.5% and 99.1%; the precisions range from 4.04% to 14.78%; and the minimum detection limits of this method are 0.02–0.20 mg/kg.

## Introduction

Many of the pesticides are used to make our lives easier. Unfortunately, a few of them are toxic. Genetic damage, reproductive problems, and possible links to cancer are just some of the risks associated with pesticides. Despite the hazards that pesticides pose to the environment and human health (especially children's health), the amount that farmers use in agriculture is ever increasing. If garments made from the agricultural products contain pesticide residues, it might be a health hazard not only to the wearers of these garments but also possibly to other family members. The disturbing reality is that according to Rebecca Spector of the Center for Food Safety of the United States, conventionally grown cotton is one of the most pesticide intensive and genetically altered crops worldwide. During pesticide application, clothing can pick up pesticide residue through spills and drift. The chemical can then enter the body through the skin. Washing contaminated garments with other clothes can contaminate the other clothes. In addition, common laundry procedures do not

remove the highly toxic and concentrated pesticide residues from clothes. Many governments and organizations are starting to regulate the maximum residue limits (MRL) of pesticides in textiles.

Although methods of testing for pesticides in some different matrixes have been developed and matured, widely accepted analytical methods of testing for pesticide residues in textile are rare. Procedures are accordingly needed to reliably and rapidly detect and quantitate as many contaminants in textile and textile materials as possible, including pesticides, in the most cost-effective manner. In this paper, analytical techniques including multiresidue analysis, effective cleaning-up, and positive confirmation, which has been accepted by pesticide analysts were applied. The procedure involves sample extraction by ultrasonic, cleaning-up by solid-phase extraction (SPE), and the final determination by gas chromatography (GC)–mass spectrometry (MS).

Forty-five pesticides out of fifty-four regulated in *Oeko-Tex Standard 100—General and Special Condition* (1), which is the technical specification from the independent test institutes of the International Oeko-Tex Association that explains the technical specification for ecological textiles, which pose no risk whatsoever to health, were covered in this method. It was decided to exclude nine pesticides regulated in *Oeko-Tex Standard 100* from this method. The nine compounds removed were: six phenoxy acid herbicides (2,4,5-T, 2,4-D, Dichlorprop, MCPA, MCPB, and Mecoprop), because they needed the extra pretreatment of methyl esterification; Dinoseb and Captafol, because they are more suitable to be detected by liquid chromatography as oppose to GC due to their relatively lower thermal liability than other pesticides detected in the GC temperature program used in this study; and Toxaphene, because it contains over 670 chemicals, which produce too many ion fragments. To increase the applicability of this method, 23 other highly toxic pesticides, which were or have been widely used but their usage in soil is now strictly limited by most countries, were included.

This method conforms to the requirements of MRL residue limit in terms of ecological textiles by most countries and authorities (1). This method can simultaneously qualify and quantify up to 77 pesticides residues including one organoni-

† Equal contribution, authors share the first authorship.

trogen, eight carbamate, 12 pyrethroid, 26 organochlorine, 30 organophosphorous compounds in textiles (see Appendix Table I).

Six kinds of textiles, representing the main categories of textiles, were selected as test samples: four kinds of natural fabrics were chosen because the limited pesticides listed in the *Oeko-Tex Standard 100* mainly aim at natural fibers and two kinds of natural and artificial mixed fibers were chosen to cover more textile products.

## Experimental

### Test samples

The test samples were: wool-adjacent fabric (GB7564); cotton-adjacent fabric (GB7565); silk-adjacent fabric (GB7568); ramie-adjacent fabric (GB13765). GB7564, GB7565, GB7568, and GB13765 are all China National Standard Textile Samples. Other test samples were: wool-viscose (50:50 white) and polyester-cotton (65:35 battle dress uniform).

### Materials and reagents

The materials and reagents used were: hexane (pesticide grade) (DIMA Technology, ON, Canada); anhydrous sodium sulfate (Analytical Reagent) (Beijing Chemical Factory, Beijing China), which were baked at 650°C for 3 h, cooled down, and stored in desiccators. Florisil cartridges were from Bestown Company (Beijing, China). Standard reference materials were: pesticides standards with purity greater than or equal to 94% and obtained from Dr. Ehrenstorfer GmbH (Augsburg, Germany), Sigma-Aldrich Co. (Seelze, Germany), and National Research Center for Certified Reference Materials (CRM)s (Beijing, China). For stock solutions: Every pesticide was dissolved with acetone, and the concentrations of the 77 stock solutions were between 500–1000 µg/mL. Mixed standard solution were made in one acetone solution including all pesticides.

### Apparatus

An Ultrasonic processor, 40 kHz, was from Kunshan Dianshanhou Testing Instrument Factory (Shanghai, China). A rotating vacuum evaporator was from Tokyo Rikakikai (Tokyo Japan). A GC-MS with a mass selective detector (MSD) and an electron impact (EI) source was from Agilent-5973I (Agilent Technologies, Palo Alto, CA).

### GC-MSD Conditions

The GC column used was a DB-5 MS (30 m × 0.25 mm × 0.1 µm, Agilent, Palo Alto, CA) or similar. The GC temperature program was: temperature of column, 50°C for 1 min, increased from 50°C to 180°C at 30°C/min, and held at 180°C for 1 min, and then increased from 180°C to 280°C at 15°C/min and held at 280°C for 20 min. The injection port temperature was 270°C. The interface between the GC and MS was 280°C. The column flow was: helium as the carrier gas with a purity over or equal 99.999%, constant at 1.2 mL/min. The ionization mode was EI. The electron energy was 70 eV. The determination mode was selected-ion monitoring (SIM). The injection volume mode

was 1 µL/pulsed splitless by the auto-injector, and the valve was opened after 1.5 min.

### Procedure

Representative samples were taken and cut into tiny pieces smaller than 5 × 5 mm. A sample (2 g) was weighed (accurate to 0.01 g) into one 100 mL stoppered Erlenmeyer flask. Hexane–ethyl acetate (1:1) (50 mL) was added, and the mixture was ultrasonicated for 20 min (2,3). The supernatant solvent was filtered, and the residue was ultrasonicated again with 30 mL hexane–ethyl acetate (1:1) for 5 min. The filtrates were combined, dehydrated with anhydrous sodium sulfate, collected into a 100 mL heart-shaped flask, and condensed in 40°C water bath under vacuum to nearly dryness using a rotary evaporator. Acetonitrile–toluene (1:3) (3 mL) was used to dissolve the residues.

The florisil cartridge was conditioned with 5 mL acetonitrile–toluene (1:3) (4,5). The extract was loaded on the cartridge. The heart-shaped flask was rinsed with 2 mL of acetonitrile–toluene (1:3) twice, and the washings were loaded onto a cartridge. The cartridge was eluted with 20 mL of acetonitrile–toluene (1:3), and the eluate was collected into a 50-mL heart-shaped flask. The eluate was evaporated to near dry using a rotary evaporator in a 40°C water bath under vacuum. Finally the residues were diluted to 2.0 mL with acetone for analysis using GC-MS.

## Results and Discussion

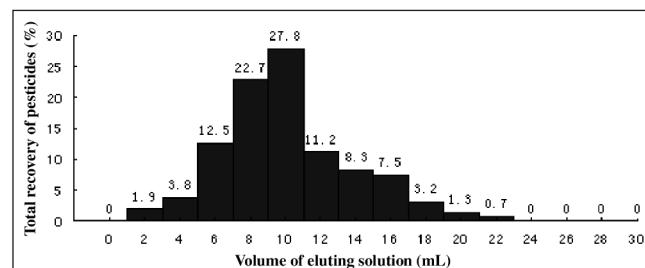

### Pretreatment

#### Extraction

The extraction was carried out twice using an ultrasonic processor with 50 and 30 mL of hexane–ethyl acetate (1:1), respectively, which is easy and fast without significant difference in results after comparison with Soxhlet extraction on wool-adjacent fabric sample (GB7564) (See Appendix Table II).

#### Clean-up

The extract of textiles contained little colorants, fat, or other impurities. A florisil cartridge was used for clean-up. The conditions of clean-up were investigated to observe the separation and purification efficiency using the florisil cartridge for the 77

**Figure 1.** The elution chart of 77 pesticides. During 0–23 mL of the eluant, the 77 pesticides were present. Collecting 23 mL of eluate could remove the influence of impurities while maintaining the recoveries of these pesticides.

pesticides in six kinds of matrixes (6).

The extractions of blank and of the six kinds of spiked matrixes were run through the florisil cartridge. The eluate was collected in 2-mL aliquots into separate tubes in sequence, and a total of 30 mL was collected. The portion in each tube was tested for the total content of pesticides, and their recoveries were calculated to ascertain the optimized time to collect the fraction (7) (Figure 1). From the elution chart, it was known that the 77 pesticides were present during 0–23 mL of the eluent, which ran through the florisil cartridge. Thus, it was proved that collecting at least 23 mL of eluate could remove the influence of impurities while maintaining acceptable recoveries. In the SPE step, 24 mL of eluant was used.

#### GC-MS conditions

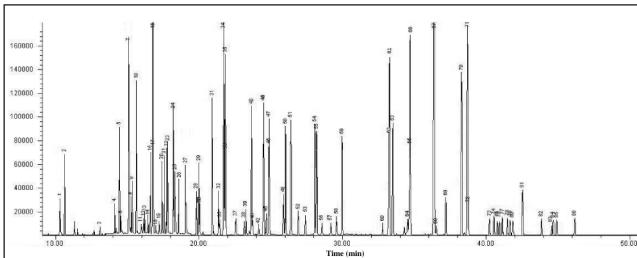

DB-5 MS (30 m × 0.25 mm × 0.1 µm) silica capillary column (4) was used for GC under the programmed temperature scheme. Techniques of pulsed splitless injection using capillary and the principal of Solvent Effects were adapted to selectively and chromatographically separate these 77 pesticides.

#### GC-MS analysis

The target and qualifier abundances were previously determined by injection of individual pesticide standards under the same chromatographic conditions in full-scan mode. GC-MS analysis was performed in the SIM based on the use of one target and three qualifier ions. Pesticides were identified according to the retention times.

As quantitation is of paramount importance, SIM is preferably employed. In the SIM mode, the mass analyzer is operated in a way that it alternately acquires only the ionic masses of interest. The scan time spent on a diagnostically useless  $m/z$  range is almost reduced to zero, whereas the detector time for the ions of interest is increased by a factor of 10–100. So an improvement in sensitivity is observed, and peak resolution, accuracy, and precision were also improved. If increasing the number of ions monitored decreases the sensitivity, the run time was prolonged in order to achieve enough sensitivity for a high number of pesticides. The emphasis was, therefore, on separation rather than fast analysis.

A previous full GC-MSD scan had been performed, and the total ion chromatogram (TIC) of the 77 pesticides was available.

**Figure 2.** The GC-MS-SIM chromatogram obtained for the standards of the 77 pesticides. 86 peaks appeared in the SIM chromatogram because some of the 77 pesticides possess isomeric forms. They are Chlorfenvinphos Z and E (38th and 40th peaks), Permethrin I and II (70th and 71st peak), Cyfluthrin I, II, III and IV (73rd–76th peaks), Cypermethrin I, II, III and IV, (77th–80th peaks), Fluvalinate I and II (84th and 85th peaks).

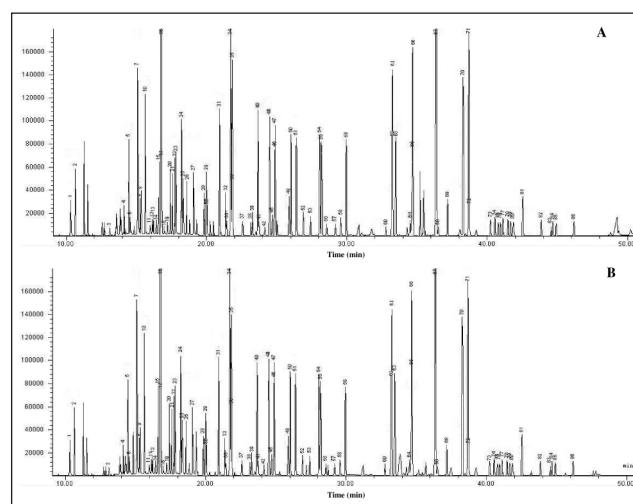

The fragment ions ( $m/z$ ), which had higher abundances and larger masses were selected, and GC-MSD was changed to SIM mode. Table III (see Appendix) lists the pesticides' quantitation ions and qualifier ions. The SIM parameters are described in Table IV (see Appendix).

Using chromatographic and spectrometric methods, GC-MS-SIM chromatogram of the 77 pesticide standards are generated, which is shown in Figure 2. The peak sequence with retention times are shown in Table III (see Appendix). Figures 3A and 3B show the SIM chromatogram of two spiked samples: wool-adjacent fabric and cotton-adjacent fabric, respectively. There are 86 peaks that appeared in the SIM chromatogram because some of the 77 pesticides posses isomeric forms. There are 86 peaks that appeared in the SIM chromatogram because some of the 77 pesticides posses isomeric forms. They are Chlorfenvinphos Z and E (38th and 40th peaks), Permethrin I and II (70th and 71st peak), Cyfluthrin I, II, III, and IV (73rd–76th peaks), Cypermethrin I, II, III and IV, (77th–80th peaks), Fluvalinate I and II (84th and 85th peaks).

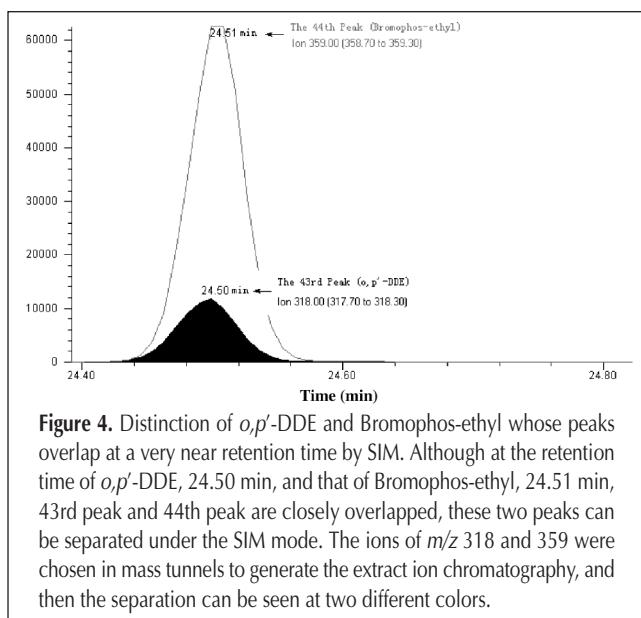

Using the external standard method, quantitation was achieved by comparing the peak areas of test samples to that of standard references in the SIM chromatograph. Positive confirmation of the pesticides was based on the retention time of the featured quantitation ion and on the abundance ratio of three qualifier ions. Identity of a pesticide was confirmed when its retention time matched the retention time of the pesticide standard within  $\pm 0.05$  min. The abundance ratio was determined by dividing the abundance of the selected confirmation ion by the quantitation ion and multiplying by 100. Where no interference was observed, the relative SIM responses of each of the ions monitored for the analyte should correspond to those obtained from a standard (within  $\pm 20\%$ ).

#### Separation and quantitation of overlapped peaks

It was a difficult task using a 30-m long capillary column to separate all 77 pesticides. Some peaks were the result of the

**Figure 3.** SIM chromatogram of spiked wool-adjacent fabric sample (GB7564). All peaks of 77 pesticides are available and no obvious disruptive peaks are found (A), and SIM chromatogram of spiked cotton-adjacent fabric (GB7565). All peaks of 77 pesticides are available and no obvious disruptive peaks are found (B).

**Figure 4.** Distinction of *o,p'*-DDE and Bromophos-ethyl whose peaks overlap at a very near retention time by SIM. Although at the retention time of *o,p'*-DDE, 24.50 min, and that of Bromophos-ethyl, 24.51 min, 43rd peak and 44th peak are closely overlapped, these two peaks can be separated under the SIM mode. The ions of *m/z* 318 and 359 were chosen in mass tunnels to generate the extract ion chromatography, and then the separation can be seen at two different colors.

overlapping of more than one analyte. For instance 29th and 30th, 43rd and 44th, 48th and 49th, 65th and 66th, etc. However SIM mode can distinguish these overlapped peaks which represent different pesticides.

An example of how different pesticides peaks overlapped is shown in Figure 4. In the chromatogram, the retention time of *o,p'*-DDE, 43rd peak (24.50 min), and that of Bromophos-ethyl, 44th peak (24.51 min), are closely overlapped. To accurately quantify these two pesticides, their ionic fragments in the full scan mode were investigated, in which *o,p'*-DDE had a maximum featured ion *m/z* 318 and Bromophos-ethyl had one at *m/z* 359. Under the SIM mode, *m/z* 318 and 359 were chosen in mass tunnels to generate the extract ion chromatography to separate these two peaks, and quantitation can then be employed (8).

#### Linearity

Using the stated GC conditions, the standard references of total 77 pesticides were determined in a certain concentration range. The correlation coefficients  $\gamma$  are between 0.9943–0.9987.

#### Determination of minimum detection limits

The minimum detection limits (MDL) for each pesticide of this method is derived from the values of the detection sensitivity (the ratio of signal to noise is over 3) of GC-MS and the responded value to the given sample matrixes. As is shown in the Appendix Table III, MDLs ranging from 0.02–0.20 mg/kg are qualified to the regulated limit of textiles according to *Oeko-Tex Standard 100*.

#### Accuracy

Six kinds of blank samples were spiked with the 77 pesticides at 0.500 and 2.00 mg/kg to determine their recoveries. Each sample was injected 5 times with an automatic injector at each level. The average recoveries at the level of 0.500 mg/kg were between 65.3–94.0%, and at 2.00 mg/kg they were between 64.5–99.1%, respectively, with the great majority greater than

80%. The obtained precisions determined under repeating conditions and expressed as coefficient of variation (CV) at the level of 0.500 mg/kg were 4.04–17.47% and at the level of 2.00 mg/kg were 5.42–14.78%, respectively. All the quality control data are shown in Table V (see Appendix).

Nearly 75% of the pesticides recoveries show a better effect on silk, cotton, and ramie than on wool. The reason is that in a wool matrix, more pesticides are lost during the SPE procedure because wool has a higher oil content than other samples. There is no obvious difference between the recoveries from cotton and ramie, both of which are plants. Although silk, which contains a good deal of protein, has a more complicate composition, it gives similar recoveries to cotton and ramie.

#### Conclusion

A method has been developed for the simultaneous extraction, cleanup, and determination of 77 pesticides in textiles. The optimum conditions for extraction were 20 min and 5 min ultrasonic durations with 50 mL hexane–ethyl acetate (1:1), dehydrated, condensed, and diluted with acetonitrile–toluene (1:3) to 3 mL. The extract was run through the florisil SPE cartridge, and eluted with  $2 \times 2 + 20$  mL of acetonitrile–toluene (1:3) and the eluate was analyzed using GC-MS in SIM mode. The quantitation was carried out using external standards.
