## SUMMARY

Reduced retention of branched-chain esters due to screening of the carboxyl group is reported by considering the retention behaviour of the $n$ - and isoalkyl esters of pivalic and pentanoic acids on polysiloxane stationary phases of varying polar character.

## INTRODUCTION

Many workers have investigated the relationship between gas chromatographic retention and the chemical structures of the solute and solvent. Some empirical rules concerning retention with both polar and non-polar solvents and solutes have been known since the earliest works and although they have been refined to include the interactions of donor and acceptor groups in both species, these considerations would appear to be of limited general application. Elution of non-polar compounds according to boiling point or molecular weight on non-polar substrates has been extended to a study of simple esters ${ }^{1-3}$ from which it is apparent that the compounds are frequently eluted substantially following boiling point, which is influenced by the shape of the molecule and the resultant steric hindrance. With substances that are hindered, some screening of the interactive group can occur and the increased retention anticipated with the use of more polar phases is not as significant.

The present work considers the concept of screening by a study of the effect of stationary phases of increasing polar character on the retention behaviours of the $n$ alkyl pivalates, where the carbonyl group is adjacent to a tert.-butyl group, and of the

isoalkyl esters, where chain branching also occurs adjacent to the carboxyl oxygen atom.

Limited retention data of the methy ${ }^{4,5}$ and ethyl esters ${ }^{6}$ have been reported while the most extensive work by Eidus and co-workers ${ }^{7}$ showed retention plots of the $\alpha, \alpha$-dimethylalkanoic acids and of their isobutyl esters on a polar column containing $18 \%$ DEGS and $4 \%$ phosphoric acid. Plots were also shown of the $\alpha$-alkanoic, the $\alpha$-ethylalkanoic acids and of the isobutyl esters. The retention of the acids and esters of the $\alpha, \alpha$-dimethylalkanes $<\alpha$-methylalkanes $<\alpha$-ethylalkanes while the first member of the dimethyl series on both plots, i.e. pivalic acid and isobutyl pivalate, showed substantially reduced retention as compared with the other members of the series.

## EXPERIMENTAL

The retention data used were obtained isothermally at $150^{\circ}$ using $12 \mathrm{ft} . \times 1 / 4$ in. O.D. aluminium columns with $10 \%$ stationary phase on 62-72 mesh acid washed and silanized Celatom, as previously reported ${ }^{3}$.

The intercepts of the retention plots of the homologous series were calculated from the line of best fit determined by regression analysis using a simple programmable calculator.

## RESULTS AND DISCUSSION

The retention data of the esters examined are shown in Tables I and II as relative retentions ( $V_{R}$ ) using $n$-nonane as standard and as retention indices ( 1 ). Figs. 1a and Ib show retention plots of the $n$-alkyl pivalates and the normal-acid-chain esters of the same carbon number, i.e. $n$-pentanoates, respectively, on a series of polysiloxane stationary phases of varying polar character. From Fig. la, it is evident that the retention of the branched esters is significantly reduced as compared with the normal esters (Fig. 1b). The behaviour on the non-polar phases follows a boiling-point relationship as the branching causes the usual reduction in boiling point relative to the straightchain homologs. The retention of both series is increased as the polar nature of the phase is increased, although it is apparent that with the pivalates the increased retention over the range of phases is reduced. This effect, which might be expected as the polarizable groups of the esters are partially shielded from the interactive groups of the polar phases and the repulsive forces, and the solute retardation are not as great as with the straight-chain esters. The customary increased retention of methyl compounds occurs with both series of compounds.

The retention increments due to the carboxyl group of the $n$-alkyl esters on various phases have been reported previously ${ }^{3}$ and were found as the intercept of the linear retention relationship calculated from the line of best fit determined by regression analysis where the abscissa was considered as the total number of carbon atoms due to the alkyl groups. With the esters previously reported, the incremental value for the carboxyl group was observed to increase as the polar character of the stationary phase was increased, and the same effect is observed with the values determined for the pivalate series, which are shown in Table III together with values for the n-alkyl esters.

Figs. 2 a and 2 b show retention plots of the isoalkyl esters of pivalic and $n$ pentanoic acids, respectively, on the same phases. In common with the behaviour

shown in Figs. 1a and 1 b , the retention of both series is also increased as the polar character of the phase is increased. However, the increased retention over the range of stationary phases is lower than with the isoalkyl pivalates.

The increased retention due to polar interactions, i.e. $I_{\mathrm{XF}-1150}-I_{\mathrm{SE}-30}$, being greatest with the $n$-alkyl esters, and decreasing with isoalkyl esters, $n$-alkyl pivalates and isoalkyl pivalates. Incremental values for the carboxyl group of the isoalkyl esters are not shown owing to the non-linear nature of some of the plots. Also with the esters reduced retention of the isopropyl compounds occurs, as discussed previously by Allen and Haken ${ }^{8}$, and sufficient data are not available to determine a reasonable line for comparison.

Fig. 2. Retention plots of (a) isoalkyl pivalates and (b) isoalkyl pentanoates on stationary phases as shown for Fig. 1.

## ACKNOWLEDGEMENT

The sample of SILAR SCP was kindly provided by Dr. R. S. Henly of Applied Science Laboratories Inc., State College, Pa., U.S.A.
