CHARACTERIZING PETROLEUM- AND SHALE-DERIVED JET FUEL DISTILLATES VIA TEMPERATURE-PROGRAMMED KOVÁTS INDICES

P. C. HAYES, Jr.* and E. W. PITZER

AFWAL/POSF, Aero Propulsion Laboratory, Air Force Wright Aeronautical Laboratories, Air Force Systems Command, United States Air Force, Wright-Patterson Air Force Base, OH 45433 (U.S.A.)

(Received July 9th, 1982)

SUMMARY

The Kováts retention indices of nearly 200 hydrocarbons expected to be found in jet fuel distillates of petroleum and shale oils were determined on two open tubular gas chromatographic columns of different polarity under conditions of linear temperature programming. The overall precision for the indices was indicated by the mean values of the 95% confidence levels, *i.e.* ± 0.06 for the OV-101 column and ± 0.09 for the OV-17 column. Several specification JP-4 jet fuels were characterized and tentative peak assignments made.

INTRODUCTION

Commercial hydrocarbon products such as gasoline, kerosene, and jet fuels are deceptively simple in appearance but are actually a blend of literally thousands of hydrocarbons. Knowledge of the chemistry of these products, however, can yield an immense wealth of practical information. Bulk properties and characteristics such as combustion behavior, storage stability, ignitability, and toxicological effects, as well as physical and generalized chemical properties, can all be predicted from a thorough chemical breakdown of a fuel's hydrocarbon composition.

Unfortunately, detailing the myriad of hydrocarbon components in these products is unassailable by any single, though sophisticated, state-of-the-art analytical technique. What is required is a judicious meshing of highly advanced chromatographic and spectroscopic techniques applied in a sequential mode of attack. This approach is not an original idea. A typical unified system for the detailed analysis of aircraft fuels, both conventional and experimental, without regard to their type of complexity, could consist of five distinct steps that include a fuel fractionation procedure followed by high-resolution gas chromatography-mass spectrometry (GC-MS) and proton and carbon-13 Fourier Transform nuclear magnetic resonance (NMR) analyses of the individual fractions¹.

Petroleum and shale-derived jet fuels are too complex to be unraveled by even the most efficient GC column. However, multi-dimensional gas-liquid partition chromatography (GLC) appears very promising. Heart-cut segments of the total hydro-

carbon profile are diverted automatically from one capillary column to another having greater selectivity. Unfortunately, few preparative-scale work-ups from multi-dimensional cuts for subsequent analyses by NMR, infrared spectroscopy, etc. have been published.

The primary purpose of this experimental study was to establish an optimization procedure and generate statistically reliable and chromatographically sound retention libraries of a large variety of pure reference hydrocarbons. Retention indices can be used to assign, with high probability, tentative identifications of the major components in JP-4 aircraft fuel. Furthermore, the indices can provide an authoritative judgement as to the integrity of separated fractions from any proposed preparative method of fractionating hydrocarbon fuels.

In their foundational article on GLC, James and Martin² proposed that both the retention volume and the retention time of a solute can be characteristic and an aid in its identification. The "retention index" system introduced by Kováts calculates the logarithmic retention of a solute interpolated between those of two standard compounds³. Any homologous series of organic compounds can be used as the standards. This system has proved especially well suited for the standardization of GC retention data. The Kováts system has proven so useful that the Discussion Group of the Institute of Petroleum recommended its use in the standardization of retention data⁴.

Van den Pool and Kratz⁵ have demonstrated that for a temperature-programmed GC run, the logarithmic relationship which exists under isothermal operation is replaced by the approximately linear relationship⁶:

$$I_{PT}^C = 100 \left[\frac{t_R(\text{unknown}) - t_R(C_z)}{t_R(C_{z+1}) - t_R(C_z)} \right] + 100 z$$

where I_{PT}^C is the retention index of the unknown compound as determined on stationary phase C under conditions of linear temperature programming, $t_R(\text{unknown})$ is the absolute retention time of the unknown compound, $t_R(C_z)$ is the absolute retention time for the *n*-alkane that elutes prior to the unknown, $t_R(C_{z+1})$ is the absolute retention time for the *n*-alkane that elutes just after the unknown, and z is the number of carbon atoms in the *n*-alkane standard that elutes just prior to the substance of interest.

The Kováts Index unit is characteristically determined by the type and thickness of stationary phase liquid, the mobile phase, the molecular structure of the component of interest, and the temperature-programming rate.

However, in a linear temperature-programmed chromatogram, the retention data are not strictly linear for the *n*-paraffinic series. In the region of the lower paraffins, including hydrogen, the linearity is not very good⁷. Yet numerous investigators have utilized retention indices based on the *n*-paraffins^{5,8,9}, and other homologous series^{7,10,11} under temperature-programmed conditions. An alternate homologous series enables the use of detectors which are not sensitive to *n*-paraffins, e.g. *n*-alkyl trichloroacetates with an electron-capture detector or *n*-alkylbenzenes for an ultraviolet detector¹².

EXPERIMENTAL

The analyses were performed on a Varian Model 3700 capillary gas chromatographic system equipped with dual flame ionization detectors, a Varian 1070 all-glass injector in the split mode configuration, and fitted with a Varian 8000 automatic liquid sampler¹³. A Varian Model CDS-111 computer integrator controlled the automatic liquid sampler, the temperature programming and the data collection, and continuously monitored the system parameters. Chromatographic operating conditions, *e.g.* linear flow-rate, programming rate, initial column temperature, etc., were optimized for maximum resolution between the C₁₁ and C₁₂ *n*-alkanes in a reasonable analysis time since historically, this is the region of poorest separation in a JP-4 fuel chromatogram¹⁴. Those operating conditions are summarized in Table I.

TABLE I

CHROMATOGRAPHIC OPERATING CONDITIONS FOR THE OPEN TUBULAR GLC COLUMNS

Detector	Flame ionization detector
Detector temperature	300°C
Injector	Fritted glass insert (normal split mode)
Injector temperature	300°C
Liquid sample volume	1.0 μ l, split 1:50 (diluted 1:100 prior w/CS ₂)
Septum purge flow-rate	25 ml/min
Detector make-up flow-rate	30 ml/min
Detector hydrogen flow-rate	30 ml/min
Detector air flow-rate	300 ml/min
Columns	OV-101 and OV-17, both 0.25 mm I.D., both <i>ca.</i> 110 m long, both <i>ca.</i> 0.2 μ m film thickness
Carrier gas (helium) flow-rate (average linear velocity)	29.18 cm/sec (OV-101), 25.38 cm/sec (OV-17); $t_0(\text{CH}_4) = 6.23 \text{ min (OV-101), 7.69 min (OV-17)}$
Column temperature profile	Initially 35°C, immediately programmed at 1°C/min to a final temperature of 200°C
Electrometer range	4 \cdot 10 ⁻¹² A/mV

Column efficiencies were measured and found to be in excess of 225,000 effective theoretical plates in each case. A 0.1% (w/w) solution of *n*-C₁₃ (capacity factor, $k' = 3.97$) in CS₂ was used to make the measurement. It has been pointed out that for identification using Kováts indices at high precision, open tubular columns of high resolution with effective theoretical plates of at least 50,000 should be used¹⁵. For this experimental study, the columns exhibited nearly five times this number of useable plates.

To avoid potential contamination problems, ultra-high-purity helium (99.999%) was used as the carrier gas. The helium was passed through a Hydrox Purifier, Model 8301 (Matheson Gas Products) to remove residual oxygen and/or water vapor present to less than 0.1 ppm each. The permeation of air and moisture and organic contamination, *i.e.* back-diffusion, was eliminated by the use of metallic diaphragm regulators¹⁶.

Column capacity also had to be considered. Progressive column overloading

causes typical "leading" peak shapes and shifting in retention index values. Symmetrical peaks can be obtained by lowering the sample load. Schomburg and Dielmann¹⁷ defined the "linear dynamic range of precise index determination" as the range limited by the smallest sample the detector can see (usually taken as twice the noise level) and the maximum sample load which does not give asymmetric peaks. GC-analyzed standards (nearly all purchased from Wiley Organics, Columbus, OH, U.S.A.) and jet fuels were diluted nearly 100:1 in a relatively non-interfering solvent (CS_2) to limit the amount of the most predominant hydrocarbon species entering the columns to less than 10 ng each.

RESULTS AND DISCUSSION

The method of applying the Kováts indices used in this report was to identify substances in fuel samples by matching their indices as determined on two capillary columns of different polarity against two corresponding libraries of over 200 standard hydrocarbons each. An identification window was established for each standard hydrocarbon on each polarity column and applied to suspect peaks in unknown fuel samples. Of course, all such qualitative judgements on compound identity were tentative and will later be checked by GC-MS. It was also feasible to predict the identity of major hydrocarbon fuel components that had not been included in the pure standards. Plots of retention indices *versus* carbon number of different homologous groups, *e.g.* 2-methylalkanes, *n*-alkylbenzenes, 1-olefins, *n*-alkylcyclohexanes, *etc.* all displayed a high degree of correlation¹⁴. These assignments can be considered entirely reasonable, but acquisition of the pure standard is always the final confirming route.

The collections of Kováts retention indices for both the OV-101 and the OV-17 columns are listed in Table II. The compounds are listed numerically by their OV-101 Kováts indices from five glass capillary GC runs. These numbers are accompanied by their standard deviations and 95% confidence levels for five determinations. A Kováts index could not be computed for all compounds on both columns, due to peak coelution with other standard compounds, *n*-alkanes, or the solvent.

The overall precision for these computations is indicated by the mean values of the 95% confidence levels, *i.e.*, ± 0.06 for the OV-101 column and ± 0.09 for the OV-17 column. It should be noted that the 95% confidence levels of the low boiling compounds are much larger than those of the other compounds. This is a direct result of the shorter retention times of the low boiling compounds, where a slight difference in retention times for repeat runs has a larger effect on the 95% confidence level than the same absolute difference has for higher boiling components with much longer retention times.

Samples of both petroleum-derived and shale-derived jet propulsion fuels were prepared in solution with CS_2 at a dilution ratio of 1:100. These samples were then analyzed three times each on both the OV-101 and the OV-17 columns under the same conditions used for the standard solutions of the Kováts libraries. The Kováts index for each peak of the fuel samples was then calculated and statistically analyzed at the 95% confidence level for three determinations (see Tables III and IV).

During the preparation of the standard solutions it was noticed that the glass capillary GC system, under the conditions of this experiment, could not resolve two compounds, placed in the same solution, whose Kováts index differed by less than

TABLE II

KOVATS INDICES GENERATED ON TWO QUADREX CAPILLARY COLUMNS: COLUMN 510B, 108M OV-101; COLUMN 1029A, 117M OV-17

* 95% Confidence limit for three determinations = $\frac{4.303 \sigma}{1.732}$.

one unit. Therefore a tentative assignment interval of ± 0.5 Kováts index unit was used for matching indices.

After all peak assignments were complete, a precision survey was performed on Fuel 15B (Table IV). The resulting deviations of assignments from the true library values, ± 0.127 for the OV-101 and ± 0.180 for the OV-17, indicate that the assignments were well within the ± 0.5 assignment interval.

The preceding tables list the two jet propulsion fuels selected for this article. The peaks tentatively identified in each fuel are listed numerically by their OV-101 library indices. "K.I.-samp." represents the mean Kováts index for the three runs of a sample on the particular column and is accompanied by the standard deviation and 95% confidence level for three determinations. "K.I.-101" and "K.I.-17" represent library Kováts index values for the known reference standards. "A %" indicates the area percent of an identified peak from the first run of the fuel sample. Area percent is not intended to determine quantitatively the component but is used merely as a comparison tool to aid in the qualitative identification of peaks. For example, in shale-derived JP-4 Fuel 15B (see Table IV), the area percent of the peak thought to be 2-methylhexane is 0.45 A % on the OV-101 column and 0.44 A % on the OV-17 column. This comparative relationship lends additional credibility to the Kováts index matching process.

The asterisks in the "K.I.-101", "K.I.-17", and "A %" columns indicate compounds that appear to have coeluted. The asterisked number in the "A %" column is actually the library index (*i.e.* "K.I.-101" or "K.I.-17") of the other compound with which that compound has appeared to coelute. For example, benzene and methylcyclohexane coelute on the OV-17 column. Furthermore, their OV-17 library indices, 739.24 and 739.15 respectively, both fall within the ± 0.5 assurance limit for the sample peak in petroleum derived JP-4 Fuel 1B-792009 (see Table III) having an index 739.18.

To clarify this situation, the area percents of the Fuel 1B suspect constituents, benzene and methylcyclohexane, on the OV-101 were added and compared to the area percent of the OV-17 peak suspected to be coeluting benzene and methylcyclohexane. The resulting 1.48 A % on the OV-101 compared to the 1.44 A % on the OV-17, once again indicating the usefulness of area percent when matching peaks by Kováts indices.

It must be pointed out, however, that these area percent relationships become increasingly difficult to observe in the middle of the distillation range of any given fuel sample. This is due primarily to the increased number of isomeric compounds existing in that boiling range and the present inability of the GLC system to resolve all of these compounds.

Figs. 1-4 are chromatograms from both the OV-101 and OV-17 columns for the fuels selected for display in this report. Other petroleum derived JP-4 fuels not reported here¹⁴ illustrated a need for the detailed characterization of jet fuels. Those fuels supposedly represented the same fuel only sampled at different points in a fuel handling system. Inspection of the chromatograms readily indicated that the samples were indeed different. Extensive Kováts index libraries enable one to discern exactly how fuel samples differ.

Due to the countless number of compounds existing in a complex hydrocarbon mixture such as jet propulsion fuel, it is necessary to have a method better than

random choice initially to select standards for a comprehensive library. The initial method used in this article was literature research of other glass capillary GC and detailed MS experiments performed on selected JP-4 jet propulsion fuels.

Next, the Kováts indices of members of homologous series generally varied in their Kováts indices by a set number of units. By generating linear graphs it was easy to estimate the Kováts index of a member of a homologous series given its carbon number or its boiling point. This method should by no means be used to identify components reliably, but can be used as a valuable tool in helping to choose reference compounds to extend an existing Kováts indices library. Table V demonstrates the usefulness in extrapolating the linear relationship of a homologous series to predict the presence of a member not among the reference standards. A fuel was selected at

* Relatively large area percent here suggests this component co-eluted with another hydrocarbon.

random. Indices were calculated from the corresponding carbon number *versus* Kováts indices plot and compared with a sample component having nearly the same retention index. In all cases, a peak predicted on the OV-101 column was also successfully predicted on the OV-17 column.

From the existing Kováts libraries it was noted that there were some "gaps" in the tentative identification of components found in the fuel samples. By procuring compounds of classes common to jet propulsion fuel (*e.g.* branched alkanes, alkyl-benzenes, *etc.*) whose carbon numbers fall within these "gaps", the likelihood of identifying more compounds in the fuel could also be significantly increased. This is

particularly true for the shale-derived fuel consisting of nearly 30% by volume of cycloparaffins, as determined by MS.

Another useful feature of these Kováts libraries on different stationary phases is that an unknown compound, if sufficiently resolved on both columns could be assigned to a general hydrocarbon class by calculating its difference in index values, *i.e.* $\Delta K.I.$ values. In general, branched alkanes demonstrated a rather small negative $\Delta K.I.$ of *ca.* -3 to -10 units with substantial negative values for highly substituted alkanes. Cyclohexanes usually displayed a positive $\Delta K.I.$ of *ca.* +24 units for the standards included in the libraries. The dimethylcyclohexanes averaged *ca.* +26 units while the trimethylcyclohexanes averaged *ca.* +18 units. The 1-olefins examined showed a positive $\Delta K.I.$ of +96 units. However, certain substitutions gave $\Delta K.I.$ values in the +110-120 and higher range: three or more alkyl groups in the 1, 2 and 3 positions; or two alkyl groups in the 1 and 2 positions where one group was other than a methyl; or three or more alkyl groups in the 1, 2 and 4 positions. It appears that substituents that render the hydrocarbon molecule more spherical or spheroid in shape tend to exhibit higher positive $\Delta K.I.$ values. The few alkylate 1 naphthalenes investigated showed a positive $\Delta K.I.$ of almost +201 units.

CONCLUSIONS

The Kováts retention indices of nearly 200 reference hydrocarbons have been determined in a statistically reliable fashion on two open tubular GC columns of different stationary phases. The libraries are extremely valuable in characterizing jet fuel distillates derived from petroleum and shale oils.

Crucial to investigating hydrocarbon distribution in wide-boiling fuels is optimizing column resolution. A major stumbling block in GC-MS peak identification is the coelution of peaks¹⁸, especially in the middle of the distillation range of a jet propulsion fuel. Additional resolution of components on each of the stationary phases would greatly diminish this problem.

To this end, the future effort will be geared toward coating fused silica columns of relatively narrow bore, *i.e.* 0.10 mm I.D. Lower inherent chemical adsorptivity would be gained besides increased mechanical flexibility, which allows optimum positioning of the column in relation to the injector and detector. Furthermore, the decrease in internal diameter would translate into a proportional increase in the number of effective theoretical plates available (at the column's optimum flow-rate). Coupling improved open tubular gas chromatographic resolution to prior sample fractionation by preparative, high-performance liquid chromatography would constitute a powerful analytical approach to a detailed jet fuel characterization. However, all retention index identifications would be tentative and ultimately verified by GC-MS.

ACKNOWLEDGEMENT

We thank Mr. Stephan M. Wolancyk for his substantial technical assistance, Ms. Elizabeth Tate and Mr. Dwayne Burns for reducing the data, and Ms. Lynne Schoen for tabulating the results. Particular gratitude is extended to Mr. Wayne R. Ruby, a chromatographer with the University of Dayton Research Institute, Dayton, OH, U.S.A. for his stimulating lectures and guidance.
