### SUMMARY

The gas chromatographic separation of halogenoacetates of  $C_1-C_{16}$  aliphatic alcohols and 2-halogenoethyl esters of  $C_2-C_{16}$  aliphatic acids and comparisons of retentions of pairs of these esters having the same molecular weights has been studied on SP-400 glass capillary columns. The influence of the type of halogen atoms, their number and their positions in esters on their retention was examined. Kováts retention indices were used to interpret the results.

### INTRODUCTION

The identification of halogenated esters that contain halogen atoms in either the alcohol chain, the acid chain or both is carried out by chemical reaction and by the identification of both parts of the esters'. This identification can be carried out with or without previous hydrolysis.

In the preparation of derivatives and the hydrolysis of halogenated esters, it must be taken into consideration that the halogen atoms in the ester molecule may be unstable and easily replaced with different functional groups, such as hydroxyl groups. Dehydrohalogenation can occur in some instances and the identification may be complicated or impossible. The methods used for the preparation of derivatives of both parts of esters are chosen so that their identification can be carried out by classical methods<sup>1</sup> or more modern methods involving separations<sup>2,3</sup> or their combination with spectral techniques<sup>4</sup>. This paper describes the gas chromatographic (CC) separation and identification of halogenated esters and the comparison of retentions of pairs of halogenated esters with the same molecular weights but differing as molecular "mirror image", i.e. having the same carbon atom number and positions

of the halogen atoms in the acid chains of halogenoacetates as in the alcohol chains of 2-halogenoethyl esters. The retentions of "mirror" pairs of esters of two homologous series have been studied, such as monochloroacetates of n-alkanols and 2-chloroethyl esters of n-alkanoic acids, monochloroacetates of isoalkanols and 2-chloroethyl esters of isoalkanoic acids, trichloroacetates of n-alkanols and 2,2,2-trichloroethyl esters of n-alkanoic acids, trichloroacetates of isoalkanols and 2,2,2-trichloroethyl esters of isoalkanoic acids, etc.

The principle of the study can be seen more clearly from the following structural formulae:

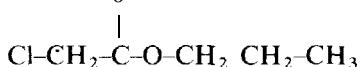

0

etc. Looking at the formulae of pairs of halogenated esters with the same molecular weights, a "mirror" arrangement of the carbon atoms and the positions of the halogen atoms in the acid and the alcohol chains is evident to when imagining the mirror at the location of the alcohol oxygen.

We have previously dealt with the GC separation of these pairs of halogenated esters on packed columns under isothermal conditions++. The GC separation of various types of unhalogenated homologous series of lower esters on packed columns was studied in great detail by Haken and co-workers<sup>9</sup>.

A better separation efficiency is achieved on capillary columns, so we used an appropriate glass capillary column under isothermal conditions for the GC separation of halogenated esters<sup>10,11</sup>. Because of the imperfect separation of halogenated esters, capillary CC with temperature programming coupled with mass spectrometry was used<sup>12</sup>. Recently, a systematic GC separation of homologous series of various chlorinated esters on glass and silica capillary columns with temperature programming was reported by Korhonen<sup>13-15</sup>, and Haken and co-workers<sup>16,17</sup>, who compared the retentions of homologous esters with the same carbon number in the alcohol and the acid chains.

In this work, model mixtures of homologous series of C<sub>1</sub>-C<sub>16</sub> n-alkyl and C<sub>3</sub>-C<sub>5</sub> isoalkyl acetates (Ac), monochloroacetates (MClAc), dichloroacetates (DClAc), trichloroacetates (TClAc), monobromoacetates (MBrAc), monoiodoacetates (MIAc) and trifluoroacetates (TFAc) and methyl esters (MetE), ethyl esters (EtE), 2-chloroethyl esters (MCIEtE), 2,2,2-trichloroethyl esters (TCIEtE), 2-bromo-

ethyl esters ( $\text{BrEtE}$ ) and 2-iodoethyl esters ( $\text{IEtE}$ ) of  $n\text{-C}_2\text{-C}_{16}$  and  $\text{iso-C}_4\text{-C}_6$  aliphatic monocarboxylic acids have been separated.

## EXPERIMENTAL

GC separations were carried out on a Fractovap Model 2 150 gas chromatograph (Carlo Erba, Milan, Italy) equipped with a flame-ionization detector and an SP-400 glass capillary column. This column was made in our laboratory from soft Unihost soda-lime glass etched with methyl 2-chloro-1,1,2-trifluoroethyl ether vapour, statically silylated with dimethyldichlorosilane vapour and dynamically coated with SP-400 silicone stationary phase. The column efficiency was found to be: capacity ratio,  $k = 2.94$  and number of theoretical plates,  $N$ , per metre = 4020 for  $n$ -decane, with "Trennzahl",  $TZ = 40.5$  for  $n$ -nonane and  $n$ -decane.

First, all of the homologous series of lower halogenated esters were separated on a  $37 \text{ m} \times 0.16 \text{ mm}$  I.D. column, then the column was divided into two lengths of 16 and 21 m. All of the homologous series of the higher halogenated esters were separated on the shorter 16-m column. Nitrogen was used as the carrier gas at a flow-rate 10 100 cm/sec with a splitting ratio of 1:100. The column temperature was maintained at  $80^\circ\text{C}$  for the separation of the lower  $\text{C}_1\text{-C}_6$   $n$ -alkyl and  $\text{C}_3\text{-C}_5$  isoalkyl halogenoacetates and 2-halogenoethyl esters  $n\text{-C}_2\text{-C}_6$  and  $\text{iso-C}_4\text{-C}_6$  monocarboxylic acids, and at  $200^\circ\text{C}$  for those of the higher  $\text{C}_6\text{-C}_{16}$   $n$ -alkyl halogenoacetates and 2-halogenoethyl esters of  $n\text{-C}_2\text{-C}_{16}$  monocarboxylic acids. The temperatures of the injector and the detector were  $250$  and  $300^\circ\text{C}$ , respectively, for the separation of the higher halogenated esters. The dead time was determined by the injection of methane.

Model mixtures of the lower and higher halogenated esters were obtained from the individual esters. Unhalogenated esters were prepared by the usual sulphuric acid-catalysed esterification and halogenated esters by azeotropic esterification.

## RESULTS AND DISCUSSION

The influence of chlorine, bromine and iodine atoms introduced into the alcohol chain of 2-halogenoethyl esters of  $n\text{-C}_2\text{-C}_{16}$  and  $\text{iso-C}_4\text{-C}_6$  carboxylic acids, the increasing length or branching of the acid carbon chain of esters, the influence of these on the acid chain of  $\text{C}_1\text{-C}_{16}$   $n$ -alkyl and  $\text{C}_3\text{-C}_5$  isoalkyl halogenoacetates and the increasing length or branching of the alcohol carbon chain of esters was studied for "mirror image" halogenated esters with the same molecular weight using retention index increments (see Tables I-IV).

The retention index increments,  $\Delta I_{\bar{x}}, \Delta I_{3\bar{x}}^*$ , for chlorine, bromine, iodine and three chlorine atoms were calculated as the differences between the retention indices for 2-chloro-, 2-bromo-, 2-iodo- and 2,2,2-trichloroethyl esters of aliphatic carboxylic acids and those for the corresponding unhalogenated ethyl esters, such as for 2-bromoethyl esters of propionic acid,  $\Delta I_{\bar{\text{Br}}} = I_{\text{BrEtEC}_3} - I_{\text{EtEC}_3}$ . The retention index increments,  $\Delta I_x$  for chlorine, bromine and iodine atoms,  $\Delta I_{2x}$  for two chlorine atoms and  $\Delta I_{3x}$  for three chlorine and fluorine atoms, were calculated as the differences in

---

\* The increments marked with a bar belong to halogen atoms and methylene groups in the alcohol chain of the esters.

| TFAcisoC <sub>4</sub>  | 630.30   | 100.63            | -139.42              | —               | —                | —                  |
| TFAcisoC <sub>5</sub>  | 731.99   | 101.69            | -141.29              | —               | —                | —                  |

the retention indices for halogenoacetates and those for the corresponding unhalogenated acetates, such as for n-propyl monobromoacetate,  $\Delta I_{Br} = I_{MBrAcC_3} - I_{AcC_3}$ . The retention increments,  $\Delta I_{HCl}$  for the second chlorine atom introduced into the monochloroacetate molecule and  $\Delta I_{H_2Cl}$  for the third chlorine atom introduced into the dichloroacetate molecule, were calculated as the differences in the retention indices of the corresponding dichloroacetates and monochloroacetates, and trichloroacetates and dichloroacetates, such as for ethyl dichloroacetate,  $\Delta I_{HClCl_2} = I_{DClAcC_2} - I_{MCIAcC_2}$ , and for ethyl trichloroacetate,  $\Delta I_{H_2ClCl_2} = I_{TCIAcC_2} - I_{DCIAcC_2}$ .

The retention index increments  $\Delta I_x$ ,  $\Delta I_{2x}$ ,  $\Delta I_{3x}$ ,  $\Delta I_x$  and  $\Delta I_{3x}$  decrease with increasing length of the alcohol or acid chains for all the homologous series of the lower halogenated esters. The decreases in these increments are greater and sharper for *n*-C<sub>1</sub>-C<sub>6</sub> alkylhalogenoacetates, whereas those for 2-halogenoethyl esters of *n*-C<sub>2</sub>-C<sub>6</sub> carboxylic acids are smaller and more gradual. A gradual and small decrease in retention index increments for halogen atoms is observed for both types of homologous series of lower halogenated esters with branched carbon chains. The retention index increments for chlorine atoms gradually decrease in the order alkyl monochloroacetates ( $\Delta I_x$ ), alkyl dichloroacetates ( $\Delta I_{2x}$ ) and alkyl trichloroacetates ( $\Delta I_{3x}$ ). The decreases in the retention index increments,  $\Delta I_x$ , for homologous series of C<sub>1</sub>-C<sub>6</sub> *n*-alkyl monochloroacetates, monobromoacetates and monoiodoacetates are approximately the same (10-12 units).

The decreases in retention index increments  $\Delta I_{Cl}$  and  $\Delta I_{3Cl}$  increase for homologous series of 2-halogenoethyl esters of C<sub>2</sub>-C<sub>6</sub> carboxylic acids with increasing number of chlorine atoms in the ester molecules, i.e., they are higher for 2,2,2-trichloroethyl esters than for 2-chloroethyl esters. The decreases in retention index increments  $\Delta I_x$  for homologous series of 2-chloroethyl esters, 2-bromoethyl esters and 2-iodoethyl esters of C<sub>2</sub>-C<sub>6</sub> carboxylic acids are approximately the same (1-6 units). For both types of homologous series of higher halogenated esters, the retention index increments do not change very much. The absolute values of the retention index increments  $\Delta I_{3x}$  for fluorine atoms decrease for the whole homologous series of trifluoroacetates.

TABLE 11

RETENTION INDICES,  $I$ , OF HALOGENOETHYL ESTERS OF LOWER CARBOXYLIC ACIDS AND INCREMENTS OF RETENTION INDICES FOR METHYLENE AND HALOGEN GROUPS AT 80°C

| <i>Ester</i>            | <i>I</i> | $\Delta I_{\text{CH}_2}$ | $\Delta I_{\bar{x}, \overline{3x}}$ | $\Delta I_{\overline{3x}} - \Delta I_{\bar{x}}$ |

Special attention was paid to halogenoesters with the same molecular weights but differing as molecular "mirror image" at the carbon atoms and the positions of the halogen atoms in the alcohol and the acid chains. To determine the influence of the number and position of individual halogen atoms in these types of halogenated esters, we calculated differences,  $D$ , between retention indices for pairs of alkyl halo-

TABLE IV

RETENTION INDICES,  $I$ , OF HALOGENOETHYL ESTERS OF HIGHER CARBOXYLIC ACIDS AND INCREMENTS OF RETENTION INDICES FOR METHYLENE AND HALOGEN GROUPS AT 200°C

| Ester                 | $I$     | $\Delta I_{CH_2}$ | $\Delta I_{X,3X}$ | $\Delta I_{3X} - \Delta I_X$ |

genoacetates and 2-halogenoethyl esters carboxylic acids (Tables V and VI). In the tables, values of  $D$  calculated from our earlier papers<sup>5-8,10,11</sup> are compared with those calculated from the paper of Haken and Srisukh<sup>9</sup>. With increasing number of chlorine atoms or atomic weights of the halogen atoms in the pairs of halogenated esters, the differences,  $D$ , decrease on the stationary phases used. The separations of these pairs of esters decrease on capillary columns under isothermal conditions.

As expected, the application of capillary columns of medium length did not

substantially increase the differences,  $D$ , in comparison with our earlier results on packed columns. The comparison of retention index increments for halogen atoms in "mirror" pairs of halogenated esters,  $\Delta I_x$ ,  $\Delta I_{3x}$  and  $\Delta I_{\bar{3}x}$  (Tables I-IV), show that the values of  $\Delta I_{\bar{x}}$  and  $\Delta I_{\bar{3}x}$  are higher than the values of  $\Delta I_x$  and  $\Delta I_{3x}$  for both the lower and the higher esters, *i.e.* a halogen atom added to the alcohol chain of esters

TABLE VI

CALCULATED DIFFERENCES, *D*, IN RETENTION INDICES OF "MIRROR" PAIRS OF HIGHER HALOGENATED ESTERS

has a greater influence on the retention than the same halogen atom added to the acid chain.

The differences, which are 10–15 units for unhalogenated "mirror" pairs of esters, decrease with increasing number and atomic weights of halogen atoms in the alcohol chain of halogenated esters, in spite of the fact that the acid carbon number increases (see Tables V and VI).

These results are in agreement with those of Haken and Srisukh<sup>9</sup> and Korhonen<sup>13</sup>.
