

Note

Unified retention index of hydrocarbons separated on squalane

N. DIMOV

Chemical Pharmaceutical Institute, Sofia 1156 (Bulgaria)

(First received April 11th, 1985; revised manuscript received July 22nd, 1985)

The general identification approach applied over many years in gas chromatographic (GC) practice is to compare the retention of a compound of interest with that of a reference substance or standard. It is not easy, however, to maintain the necessary collection of standards, so comparison is commonly made with literature data. Unfortunately, the published retention data are given in many forms and their usefulness is limited. Even the Kováts retention index, I^1 , did not solve the problem, in spite of it being considered to be the most representative characteristic of retention^{2,3}, as the temperature dependence of I and its high sensitivity with respect to stationary phase composition changes^{4,5}. The temperature dependence, dI/dT , is an additional source of information about structure⁶ and is used to confirm the identification^{7,8}. Hence, the determination of its correct value is as important as the determination of the value of I itself.

Studies on the influence of the GC conditions on the retention of hydrocarbons were completed in about 1973 with the comprehensive work of Rijks⁹. He showed that the repeatability of the experimentally obtained I values could be ± 0.1 index units (i.u.) or even better. This was confirmed later for GC with temperature programming^{10,11}. Unfortunately, the inter-laboratory reproducibility remains unsatisfactory, except for a few special cases⁹. The actual discrepancies between the experimental values of I for identical compounds obtained in different laboratories in routine analysis we assume to be ± 1 i.u.^{12,13}. Cases in which these discrepancies are up to 10 i.u. or more have been explained¹³.

We consider that the observed discrepancies should not be accepted as a disadvantage of the retention index system and it is time to establish better the reliability of this identification approach. The existing uncertainty is connected with the discrepancies between the published data. We assume that the existing numerous experimental data could be unified by using them as inputs for a regression analysis. The values obtained should be more reliable and could be used for a calibration procedure in which the column would be checked in a manner similar to spectral calibration. Then the GC identification could be considered as more reliable than it is at present. This paper gives equations for the calculation of such unified retention indices. They can be used further in the comparison with the experimentally obtained I values at any analysis temperature. The equations given refer to the calculation of unified retention indices of hydrocarbons separated on squalane.

EXPERIMENTAL

Comparison of the I_{exp} of the same hydrocarbon obtained in different laboratories shows that the discrepancy varied in magnitude and sign. Such comparisons are given in the literature¹⁴, and the differences reported varied from 0.2 to 1.3 i.u. We also compare in Table I I_{exp} values taken from the publications of workers whose activity in the field is well known¹³; even greater differences were found. Hence, the question of which data are the more correct is reasonable. Any practical chromatographer who has to identify the peaks he has obtained is faced with such a question, and so does any theoretician who works on retention index pre-calculation. Thus, Altenburg compared the values of I_{calc} , calculated according to his equations¹⁵, with the I_{exp} values obtained by Evans¹⁶. Martinov and Vidgergauz¹⁷ and later Randić¹⁸ used in their comparison the I_{exp} values of Tourres¹⁹. Hammers and De Ligny²⁰ cited the I_{exp} values of Hively and Hinton²¹, and Chrétien and Dubois²² those of Rijks⁹.

We consider that the differences between the I_{exp} values of the different workers result from random errors, because in most instances they have neither equal magnitude nor the same signs. On this basis and in order to remove doubts about the choice of the literature source for I_{exp} data, and to create a bank of data with known confidence intervals, we treated all of the existing I_{exp} values statistically. If we denote the unified retention index at any analysis temperature T (°C) by UI_T , its value could be calculated by the following equation:

$$UI_T = UI_0 + (dUI/dT)T$$

where UI_0 is the value of UI_T at 0°C. Using the I_{exp} values at the corresponding temperatures and the least-squares approach, we obtain the values of UI_0 , dUI_0/dT and the standard deviations. The value of the slope, $-dUI/dT$, is of great interest: it is used for confirmation of the identification made on the basis of I^8 ,²³ it is correlated with the structure of the substance^{24,25} or it is used for the prediction the best separation temperature²⁶. The general relationship between I and temperature is

TABLE I

 I_{sq}^{70} VALUES OF SOME HYDROCARBONS AND MAXIMAL DISCREPANCES (d) BETWEEN RESULTS OF DIFFERENT WORKERS

No.	Hydrocarbon	$I^{\text{Lit.}}$	d

hyperbolic^{27,28}, but for dI/dT for non-polar substances separated on non-polar stationary phases, the linear regression gives more accurate results¹³. Experimentally obtained values of dI/dT are given in many papers, but the determinations are made over more or less limited temperature intervals^{7,19,29-31}. It is evident that the dI/dT values calculated for two or three temperatures cannot be exact. The regression equations given in this paper combine more experimental data and are considered adequate if dUI/dT is calculated from I_{exp} values obtained by at least two groups of workers and at three temperatures. In most instances, however, the data obtained relate to more than five studies. The comparison with the experimental dI/dT values of different workers is given in Table II and the advantage is clear.

The following example explains the calculations made. For cis-2-heptene, retention indices at five temperatures ($n = 5$) from two different sources are as follows: 30°C, 701.9¹⁹; 50°C, 702.5¹⁹; 70°C, 703.1¹⁹; 86°C, 704.3²⁹; and 115°C, 705.1²⁹. The equation obtained is $UI_T = 700.61 + 0.0395T$ with a standard deviation $s = 0.247$. The calculated values of UI_T agreed well with the corresponding I_{exp} values, the difference varying between +0.30 and -0.27 i.u. in the range 30–115°C. All values obtained satisfied the linear regression. If necessary, however, a statistical exclusion of wrong data should be made.

RESULTS AND DISCUSSION

The values of UI_0 , dUI/dT , s and n , the number of I_{exp} , taken in the regression are summarized in Table II. The hydrocarbons are arranged in order of increasing UI_0 . The values of dUI/dT are compared with some similar values of dI/dT quoted in the literature. If one now uses the given values for UI_0 and dUI/dT , one could calculate UI_T for the temperature of the analysis. The UI_T value obtained and that calculated according to the given s confidence limit can be used further in the identification.

If the experimentally obtained I_T value is statistically equal to UI_T , one could decide with known reliability the peak from the chromatogram to which the hydrocarbon belongs. The UI_T value gives an even better possibility. If one checks the chromatographic column with a limited set of known hydrocarbons and obtains I_{exp} equal to UI_T , one can be confident in using this column for identification purposes. We consider this test of the column to be similar to the adjusting procedure in spectroscopy.

On the basis of the above results and the discussion, we conclude that the proposed unified retention index possesses the following advantages: UI_T is a statistically obtained value and, hence, it is more reliable than any individual I_{exp} value; UI_T is characterized by a standard deviation and the calculation of the confidence interval at any desired level is possible; dUI/dT is a more reliable value than dI/dT for estimating the peak movement with temperature; and both UI_T and dUI/dT can be used as a test to check the reliability of the column for identification purposes.
