## Short Communications

Contributions intended for publication under this heading should be expressly so marked; they should not exceed about 1000 words; they should be forwarded in the usual way to the appropriate Co-editor; they will be published as speedily as possible. Publication will be quicker if the contributions are without illustrations.

Acta Cryst. (1968). B24, 1267
The crystal structure of $\mathrm{HoZn}_{3}$ * By David J. Michel and Earle Ryba, Metallurgy Section, Department of Materials Science, The Pennsylvania State University, University Park, Pennsylvania, 16802, U.S.A.
(Received 19 March 1968)
$\mathrm{HoZn}_{3}$ was found by single-crystal techniques to be isostructural with $\mathrm{YZn}_{3}$. The space group is Pnma with $a=6 \cdot 697, b=4 \cdot 366, c=10 \cdot 099 \AA$.

The crystal structure of $\mathrm{HoZn}_{3}$ has been determined by single-crystal X-ray diffraction techniques, and it was found to be isostructural with $\mathrm{YZn}_{3}$ (Sree Harsha \& Ryba, 1964). The alloy was prepared by melting stoichiometric amounts of $99 \cdot 5+\%$ holmium and $99.999 \%$ zinc in a sealed tantalum crucible. The resulting alloy contained minor amounts of two secondary phases, which suggests that $\mathrm{HoZn}_{3}$ forms by a peritectic reaction. From a Debye-Scherrer photograph ( $\mathrm{Cu} K \alpha$ radiation: $\lambda=1 \cdot 54178 \AA$ ) of this alloy, the orthorhombic lattice parameters were found from a leastsquares fit to the data, using the Nelson-Riley extrapolation function, to be $\left(25^{\circ} \mathrm{C}\right)$ :
$a=6.697 \pm 0.003, b=4.3655 \pm 0.0014, c=10.099 \pm 0.003 \AA$.
Weissenberg photographs of a well-formed single crystal from the alloy revealed that all $h k 0$ reflections with $h=2 n+1$ and $0 k l$ reflections with $k+l=2 n+1$ are absent; thus, the space group is $P n 2_{1} a$ or Pnma.

The intensities of $412 h k l$ ( $k=0$ to 6 ) reflections were measured on an equi-inclination Weissenberg counter diffractometer with Mo $K \alpha(\lambda=0.71069 \AA)$ radiation and an $\omega$ scan. Data were recorded out to $\sin \theta=0 \cdot 5$. Intensities were corrected for absorption by the crystal, a rectangular prism $0.06 \times 0.08 \times 0.25 \mathrm{~mm}$ in size, according to the method of Burnham (1966).

Since the lattice parameters and space group possibilities indicated that $\mathrm{HoZn}_{3}$ is isostructural with $\mathrm{YZn}_{3}$, a trial structure was refined on this basis, giving the positional and thermal parameters shown in Table 1. The full-matrix least-squares program of Busing, Martin \& Levy (1962), modified for the IBM System 360/67, was used, and atomic scattering factors, corrected for anomalous dispersion, were taken from International Tables for X-ray Crystallography (1962). Unit weights were assigned to all reflections. For all observable reflections, the residual, based on $F$ 's, was

* This investigation was supported by the U.S. Atomic Energy Commission. Rept. No. NYO-3560-10.
$8.4 \%$. An $h 0 l$ electron density map confirmed the correctness of the structure.
$h 0 l$ structure factors and interatomic distances are given in Tables 2 and 3, respectively. The standard deviations for the interatomic distances were calculated by taking into account the standard deviations in both the positional parameters and the lattice parameters.

The existence of $\mathrm{REZn}_{3}$ compounds ( $\mathrm{RE}=$ rare earth) has been established in the $\mathrm{Y}-\mathrm{Zn}$ (Chiotti, Mason \& Gill, 1963), Ce-Zn (Chiotti \& Mason, 1965), Dy-Zn (Sree Harsha, 1964), $\mathrm{Sm}-\mathrm{Zn}$ (Chiotti \& Mason, 1967a), and $\mathrm{Ho}-\mathrm{Zn}$ systems. Table 4 gives the available crystallographic data for $\mathrm{YZn}_{3}, \mathrm{DyZn}_{3}$ and $\mathrm{CeZn}_{3}$. Only $\mathrm{DyZn}_{3}$ and $\mathrm{HoZn}_{3}$ have so far been found to have the $\mathrm{YZn}_{3}$-type structure, but all $\mathrm{REZn}_{3}$ compounds probably have the same structure except for $\mathrm{CeZn}_{3}$, which has a slightly different structure (Lott \& Chiotti, 1966), $\mathrm{YbZn}_{3}$, which has been reported not to exist (Chiotti \& Mason, 1967b), and possibly $\mathrm{EuZn}_{3}$. The interatomic distances in $\mathrm{YZn}_{3}$ and $\mathrm{HoZn}_{3}$ are similar, but there are significant differences between them even though the CN12 radius of Ho is only $2.7 \%$ smaller than that of Y. In addition, the Ho-Ho and Y-Y distances are longer than expected, while many $\mathrm{Zn}-\mathrm{Zn}$ distances are contracted. The structure appears to be predominantly controlled by the coordination of the zinc atoms. Fig. 1 shows (a) the basic layer of the structure, which lies in a plane perpendicular to the $b$ axis, and ( $b$ ) the coordination of the Ho atoms. The zinc atoms in the basic layer form chains
of side sharing pentagons and the holmium atoms occupy the space between these chains. Adjacent layers fit together so that the holmium atoms partially occupy the holes in the centers of the zinc atom pentagons.

| * $\mathrm{YZn}_{3}: \quad$ Sree Harsha \& Ryba (1964) |  |  |  |  |  |  |  |  |

Sree Harsha (1967) has investigated the structure of $\mathrm{CeZn}_{3}$, but full details are not yet available. The lattice parameters are similar to those of the other $\mathrm{REZn}_{3}$ compounds, and it is suspected that only slight atom shifts are necessary to change the symmetry.

We would like to acknowledge the assistance of Mrs Cheryl Ailes in the collection and processing of the intensity data.

## Acta Cryst. (1968). B24, 1269

The crystal structure of tris- (2-dimethylaminoethyl)aminemanganese (II), -iron (II) and -zinc (II) bromides. By M. Di Vaira and P. L. Orioli, Istituto di Chimica Generale e Inorganica, Università di Firenze, Florence, Italy
(Received 16 April 1968)
The crystal structures of the isomorphous compounds $\mathrm{Mn}\left(\mathrm{Me}_{6} \operatorname{tren}\right) \mathrm{Br}_{2}, \mathrm{Fe}\left(\mathrm{Me}_{6} \operatorname{tren}\right) \mathrm{Br}_{2}$ and $\mathrm{Zn}\left(\mathrm{Me}_{6} \operatorname{tren}\right) \mathrm{Br}_{2}$ [ $\mathrm{Me}_{6}$ tren $=\mathrm{N}\left(\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{~N}\left(\mathrm{CH}_{3}\right)_{2}\right)_{3}$ ] have been investigated by three-dimensional X-ray analysis and refined to final $R$ values of $0.067,0.055$ and 0.065 respectively. Crystals of the three complexes are cubic, space group $P 2_{1} 3$, with $a=12 \cdot 216 \pm 0 \cdot 007,12 \cdot 185 \pm 0 \cdot 004$ and $12 \cdot 105 \pm 0 \cdot 003 \AA$ for the manganese(II), iron(II) and zinc(II) compounds respectively; $Z=4$. The three structures consist of $\mathrm{M}\left(\mathrm{Me}_{6}\right.$ tren) $\mathrm{Br}^{+}$and $\mathrm{Br}^{-}$ions, arranged in a distorted NaCl type arrangement. The coordination polyhedron about the metal atoms is a trigonal bipyramid with $C_{3}$ crystallographic symmetry. The structure is essentially identical with that of the cobalt(II), nickel(II) and copper(II) analogues. The manganese(II) compound represents the first example of pentacoordination for this ion so far described by X-ray methods. The iron(II) complex is the first structure determined by X-rays, with trigonal bipyramidal arrangement about this ion.

A series of five-coordinated high spin complexes with general formula $\mathrm{M}^{\text {II }}\left(\mathrm{Me}_{6}\right.$ tren $) \mathrm{X}_{2}$, where $\mathrm{M}^{\mathrm{II}}=\mathrm{Cr}, \mathrm{Mn}, \mathrm{Fe}, \mathrm{Co}$, $\mathrm{Ni}, \mathrm{Cu}, \mathrm{Zn}$ and $\mathrm{Me}_{6}$ tren $=$ tris-(2-dimethylaminoethyl)amine, $\mathrm{N}\left(\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{~N}\left(\mathrm{CH}_{3}\right)_{2}\right)_{3}$, and $\mathrm{X}=\mathrm{Cl}, \mathrm{Br}, \mathrm{I}, \mathrm{NO}_{3}$ or
$\mathrm{ClO}_{4}$, has been prepared by Ciampolini \& Nardi $(1966 a, b)$.
As a part of an X-ray structural investigation of the isomorphous series of the complex bromides, we have previously reported the structures of the cobalt(II) (Di Vaira
