The $\mathbf{C o}$ (III)-N bond-length in relation to the $\mathbf{C o}$ (II)- $\mathbf{N}$ bond-length. The crystal structure of hexaamminecobalt(III) iodide $\left[\mathbf{C o}\left(\mathrm{NH}_{3}\right)_{6}\right]_{3}{ }^{*}$. By N. E. Kime and James A. Ibers, Department of Chemistry, Northwestern University, Evanston, Illinois 60201, U.S.A.
(Received 29 March 1968)
Hexaamminecobalt(III) iodide, $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{I}_{3}$, crystallizes in the $\left(\mathrm{NH}_{4}\right)_{3} \mathrm{FeF}_{6}$ structure type with four formula units in the cubic space group Fm $3 m$ with $a=10.82$ (2) $\AA$. The atoms are in the following positions: Co in $4(a) ; \mathrm{I}_{1}$ in $4(b) ; \mathrm{I}_{2}$ in $8(c) ; \mathrm{N}$ in $24(e)$ with $x=0.1789$ (14); H apparently disordered. The Co-N distance, uncorrected for the effects of thermal motion, is $1.936(15) \AA$, some $0 \cdot 18 \AA$ shorter than the corresponding distance in the Co (II) complex.

The lengths of the $\mathrm{Co}(\mathrm{II})-\mathrm{N}$ and $\mathrm{Co}(\mathrm{III})-\mathrm{N}$ bonds have often been quoted (Basolo \& Pearson, 1960; Emeleus \& Anderson, 1960) as 2.5 and $1.9 \AA$, respectively. These values are based on early structure determinations from powder samples (Biltz, 1927). This difference of $0.6 \AA$ has been used to explain the slow rate of electron transfer reactions for $\mathrm{Co}(\mathrm{II})-\mathrm{Co}(\mathrm{III})$ systems compared with other systems [e.g. Fe(II)-Fe(III)]. In an earlier report (Barnet, Craven, Freeman, Kime \& Ibers, 1966) we showed that the $\mathrm{Co}(\mathrm{II})-\mathrm{N}$ and $\mathrm{Co}(\mathrm{III})-\mathrm{N}$ distances in the hexaamminecobalt complexes differ by only $0 \cdot 16 \AA$. Here we document the structure determination of $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{I}_{3}$.

The iodide salt was chosen for this study since it is cubic with m 3 m site symmetry imposed on the hexaamminecobalt (III) cation, whereas the chloride and bromide salts were found to crystallize in the monoclinic system, with no symmetry conditions imposed on the cation. The chloride salt was prepared by the method of Bjerrum \& McReynolds (1946). The iodide salt was prepared by passing the chloride salt through an anion exchange column with the iodide ion occupying the active sites. The salt was recrystallized from water. Analyses for $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{I}_{3}$ : calculated: C, $0 \cdot 0$; H, $3 \cdot 35$; N, $15 \cdot 51$. Found: $\mathrm{C},<0 \cdot 3 ; \mathrm{H}, 3.2$; $\mathrm{N}, 15 \cdot 45$.

A series of precession photographs taken with Mo $K \alpha$ radiation $(\lambda=0.7107 \AA)$ at $25^{\circ} \mathrm{C}$ confirmed that the material crystallizes with four formula units in a cubic cell of edge $10 \cdot 82(2) \AA$. Laue symmetry $m 3 m$ and the observed extinctions ( $h k l$ absent for $h+k$ odd or $k+l$ odd) are compatible with space groups $F m 3 m, F 432$ and $F 43 m$. The placement of 72 hydrogen atoms in ordered positions in any of these groups requires that 24 of these be in a special 24 -fold position. All such 24 -fold positions lead to impossible N-H distances. Since there are no violations of the space group extinctions on overexposed photographs, we conclude that the hydrogen atoms are not ordered in the structure. Conditions imposed on the anisotropic thermal vibrations of the nitrogen atom were used to distinguish between the possible space groups. For $F m 3 m$ and $F 432$ the aniso-

tropic temperature factor on the nitrogen atom is of the form $\exp \left[-\left(\beta_{11} h^{2}+\beta_{22}\left(k^{2}+l^{2}\right)\right]\right.$ whereas in $F 43 m$ the form is $\left.\exp \left[-\beta_{11} h^{2}+\beta_{22}\left(k^{2}+l^{2}\right)+2 \beta_{23} k l\right)\right]$. Refinement in space group $F 43 m$ gives worse agreement with the data and a nonpositive definite temperature factor for the nitrogen atom. For these reasons, and since the positions eventually assigned to Co, I, and N are the same special ones in all of these groups, we assign the material to the space group $\mathrm{O}_{h}^{5}-\mathrm{Fm} 3 m$.

A spherical crystal of radius 0.085 mm was prepared by grinding. This crystal was mounted parallel to its [011] axis and eleven layers of data were collected at room temperature by the equi-inclination Weissenberg method. Intensities of 361 reflections were estimated visually against a calibrated intensity strip. After correction for Lorentz and polarization effects and for absorption (linear absorption coefficient for Mo $K \alpha$ is calculated to be $87.5 \mathrm{~cm}^{-1}$ ) the data were interscaled, by comparison of common reflections, to yield structure amplitudes for 105 independent reflections.

The structure was refined by standard least-squares procedures (The programs for the CDC 3400 used in this work include local modifications of Zalkin's FORDAP, and the Busing-Levy ORFLS and ORFFE programs.) In these calculations the function $\Sigma w\left(\left|F_{o}\right|-\left|F_{c}\right|\right)^{2}$ was minimized where $\left|F_{0}\right|$ and $\left|F_{c}\right|$ are the observed and calculated structure amplitudes and where the weights $w$ were taken as $I 2 / 4 F_{o}^{2}$ for $I<20$ and as $100 / F_{o}^{2}$ for $I \geq 20$ ( $I$ is the raw intensity). The atomic scattering factors for $\mathrm{Co}, \mathrm{I}$, and N were taken from the usual tabulation (Ibers, 1962), while those for hydrogen were taken from the calculations of Stewart, Davidson \& Simpson (1965). The effects of anomalous dispersion were included in $F_{c}$ (Ibers \& Hamilton, 1964). The values of $\Delta f^{\prime}$ and $\Delta f^{\prime \prime}$ for Co and I were those computed by Cromer (1965). A trial structure based on the earlier model (Biltz, 1927) converged rapidly. In this trial model Co is in position $4(a) 000 ; \mathrm{I}_{1}$ is in $4(b), \frac{1}{2}, \frac{1}{2}, \frac{1}{2} ; \mathrm{I}_{2}$ is in $8(c)$, $\pm\left(\frac{1}{4}, \frac{1}{4}, \frac{1}{4}\right)$; and N is in $24(e), x, 0,0$ of Fm 3 m . Initial refinement without inclusion of the hydrogen atoms and with all atoms restricted to isotropic thermal motion converged to values of $R_{1}$ and $R_{2}$ of 6.7 and $8.5 \%$, where $R_{1}=\Sigma| | F o \mid-$ $\left|F_{c}\right||/ \Sigma| F_{o} \mid$ and where the weighted $R$ value or $R_{2}$ is ( $\Sigma w\left(F_{o}\right.$ $\left.\left.-F_{c}\right)^{2} / \Sigma w F_{o}^{2}\right)^{\frac{1}{2}}$. A difference-Fourier synthesis computed at

this point provided no indication of localized positions for the hydrogen atoms, but did exhibit high electron density in the general region expected. Accordingly, the $\mathrm{NH}_{3}$ ligand was assumed to be rotating freely around the $\mathrm{Co}-\mathrm{N}$ bond and the appropriate contributions of the hydrogen atoms to the structure factors were computed (Zachariasen, 1945). In this calculation the following quantities were assumed: $\mathrm{N}-\mathrm{H}=1.008 \AA ; \mathrm{Co}-\mathrm{N}-\mathrm{H}$ angle $=109.5^{\circ} ; \mathrm{B}(\mathrm{H})=$ $3 \cdot 5 \AA^{2}$. Inclusion of these contributions reduced $R_{1}$ and $R_{2}$ to 6.5 and $8.2 \%$. In a final calculation the nitrogen atom was permitted to vibrate anisotropically. (The Co and I atoms are restricted by symmetry to isotropic vibrations.) This calculation converged to the values of $R_{1}$ and $R_{2}$ of 6.3 and $8.0 \%$ and to the parameters listed in Table 1. Table 2 lists the final values of $\left|F_{o}\right|$ and $\left|F_{c}\right|$ in electrons.

It is interesting that no evidence for localized hydrogen positions could be found in this structure, whereas the hydrogen positions are localized in $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right]\left[\mathrm{CuCl}_{5}\right]$ (Raymond, Meek \& Ibers, 1968), In the latter case, of course, the hydrogen atoms are in a less symmetrical environment and moreover some $\mathrm{N}-\mathrm{H} \cdots \mathrm{Cl}$ bonding occurs. There is no evidence of $\mathrm{N}-\mathrm{H} \cdots \mathrm{I}$ bonding in the present compound, nor does one expect such bonds to be effective in stabilizing hydrogen atom positions. Thus it is only at $-42.5^{\circ}$ that the $\mathrm{NH}_{4} \mathrm{I}$ structure is ordered (Simon, Simson \& Ruhemann, 1927) by the formation of $\mathrm{N}-\mathrm{H} \cdots \mathrm{I}$ bonds.

The crystal structure of $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{I}_{3}$ is of the $\left(\mathrm{NH}_{4}\right)_{3}$ [ $\mathrm{FeF}_{6}$ ] structure type (Wyckoff, 1965). Since the hexaamminecobalt (III) ion is restricted crystallographically to have $m 3 m$ symmetry, the only structural parameter of interest is the $\mathrm{Co}-\mathrm{N}$ distance. This distance, uncorrected for thermal motion, is found to be $1 \cdot 936(15) \AA$. The values of this distance under various assumptions for thermal motion (Busing \& Levy, 1964) are: minimum, $1 \cdot 939$; riding,
1.950 ; independent, 1.972 ; maximum, $2.005 \AA$. The $\mathrm{Co}-\mathrm{N}$ distance in $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{2}$ is $2 \cdot 114(9) \AA$, uncorrected for thermal motion. The difference between the $\mathrm{Co}(\mathrm{II})-\mathrm{N}$ and Co (III)- N distances is therefore $0.18 \AA$.* Since one expects the principal motions of the atoms in the $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$ ion to be similar, this difference should be essentially independent of the effects of thermal motion. Thus arguments based on changes in the $\mathrm{Co}-\mathrm{N}$ distances used to explain the slow rates of electron transfer in these systems do not appear to be valid. More important, there is evidence that the effect of the change of spin type on the radius of cobalt is small.

We thank K. N. Raymond for preparing the trichloride salt.
