(Received 17 June 1968 and in revised form 23 August 1968)

#### Abstract

Crystals of $\mathrm{K}_{2} \mathrm{~S}_{5} \mathrm{O}_{16}$ are orthorhombic, space-group Pbcn, with $a=9 \cdot 19, b=10.891$ and $c=14.522 \AA$. The unit cell contains eight $\mathrm{K}^{+}$and four $\mathrm{S}_{5} \mathrm{O}_{16}^{2-}$ ions with the central sulphur atom on a twofold axis. As in $\mathrm{S}_{3} \mathrm{O}_{10}^{2-}$ the anion consists of a chain of $\mathrm{SO}_{4}$ pseudo-tetrahedra, sharing an oxygen atom, the $\mathrm{S}-\mathrm{O}$ bridge distances being alternately short and long. The S-O bridge bond length to the terminal group is $0.14 \AA$ greater than the single-bond length calculated by the Schomaker-Stevenson equation.

## Introduction

The investigation of compounds of the formula $\mathrm{K}_{2} \mathrm{O} . n \mathrm{SO}_{3}$ was started in order to obtain a better insight into the chemical constitution of various polysulphates formed on reaction of $\mathrm{SO}_{3}$ with $\mathrm{K}_{2} \mathrm{SO}_{4}$. During this reaction two liquid phases are formed (Weber, 1884), the upper layer being $\mathrm{SO}_{3}$. The denser layer has a composition $\mathrm{K}_{2} \mathrm{O} . n \mathrm{SO}_{3}$ with $n$ about 8 to 10 , from which upon standing, solid polysulphates with $n$ about 5 to 6 crystallize, liberating $\mathrm{SO}_{3}$.

## Experimental

A small needle (diameter about 0.2 mm ) of the very hygroscopic material was isolated and sealed in a thinwalled glass capillary. A zero-level Weissenberg photograph about [100], superposed with Al-powder lines ( $a=4.0491 \AA$ at $20^{\circ}$ ), was prepared for calibration purposes using copper radiation. The dimensions of the $b$ and $c$ axes as listed in Table 1 were derived from the glancing angles of the 0 kl reflexions by a leastsquares procedure. Owing to the needle shape, no suitable calibration photograph for computing the $a$ axis could be made. The length of the $a$ axis was derived from a precession photograph containing the $h k 0$ reflexions, with the known $b$ axis as reference. Systematically absent reflexions ( $0 k l$ for $k=2 n+1, h 0 l$ for

* Note added in proof: - Recently we found accidentally a crystal more suitable for obtaining a precise value for the $a$ axis, viz. $9 \cdot 172 \pm 0.003 \AA, 2 \%$ less than our estimate. Recalculation of the distances results in S-O distances $0.001 \AA$ shorter and S-S distances $0.002 \AA$ longer than those listed in Table 4. The angles are not significantly affected.
$l=2 n+1$ and $h k 0$ for $h+k=2 n+1$ ) uniquely determine the space group to be $P b c n$ (No.60).

A set of equi-inclination Weissenberg photographs with three different exposure times for each layer was made about [100], levels 0 to 7 , at room temperature with molybdenum radiation. The reflexions $h k 0, h k 1$ and $h k 2$ were recorded with a precession camera by use of molybdenum radiation.

The intensities of the reflexions were measured with a densitometer and converted to structure factor moduli in the usual way, with allowance for spot-shape variations. Several reflexions occuring more than once on different photographs enabled us to put all structure factors on a common relative scale. Corrections for absorption effects were deemed unneccessary.

## Determination of the structure

Initially it was not known with which of the polysulphates ( $\mathrm{K}_{2} \mathrm{O} . n \mathrm{SO}_{3}$ ) we were dealing. Since only fourfold and eightfold positions occur in the space group $P b c n$ the number of molecules per cell must be a multiple of four. Calculated density values which agree approximately with those of $\mathrm{K}_{2} \mathrm{SO}_{4}\left(2 \cdot 24-2 \cdot 61 \mathrm{~g} . \mathrm{cm}^{-3}\right)$ and $\mathrm{K}_{2} \mathrm{~S}_{2} \mathrm{O}_{7}\left(2 \cdot 27 \mathrm{~g} . \mathrm{cm}^{-3}\right)$ were found only with $n=4,5$ and $6\left(1.89,2.26\right.$ and $2.62 \mathrm{~g} . \mathrm{cm}^{-3}$ respectively).

If $n$ is odd, one sulphur atom of the anion must be at a special position, and if $n$ is even, one oxygen atom of the anion must be at a special position. The space group Pbcn offers special positions with point symmetry $\bar{I}$ or 2 . The former would require the anion to have a linear S-O-S or O-S-O arrangement which is very unlikely. It is therefore assumed that the anion has $C_{2}$ symmetry with its odd atom at the special position 4(c). Assuming an oxygen atom ( $n=4$ or 6 ) at a twofold axis, a strong Patterson peak in the plane $y=0$, representing the distance between symmetryrelated sulphur atoms bound to this oxygen atom, should be found at about $2 \cdot 9 \AA$ (cf. $\mathrm{S}_{3} \mathrm{O}_{10}^{2}$, Eriks \& MacGillavry, 1954) from the origin. Since no such peak was found, we assumed the compound to have $n=5$ and the formula $\mathrm{K}_{2} \mathrm{~S}_{5} \mathrm{O}_{16}$, with a sulphur atom at the special position 4(c).

By systematically scanning the Patterson function for Harker peaks positional coordinates were found for
two sulphur atoms and one potassium atom in the general position $8(d)$ and one sulphur atom in the special position $4(c)$.

Fig. 1. Numbering of the atoms and interatomic distances and angles in the $\mathrm{S}_{5} \mathrm{O}_{16}{ }^{2-}$ ion.

The oxygen atoms were found by Fourier analysis, starting with the structure factors the signs of which could be derived with reasonable confidence from the sulphur and potassium position found from the Patterson. The structure was further refined by the least-squares method, finally with the use of anisotropic individual temperature factors. Rather large discrepancies were found for about twenty very strong reflexions, $F_{\text {obs }}$ being systematically smaller than $F_{\text {calc }}$, indicating extinction effects. The weighting scheme was changed so as to give these reflexions a low weight (about $10 \%$ ) and the least-squares refinement was repeated till convergence. The final agreement index $R$

Fig.2. Projection of the unit cell along [010]. The $y$ axis is pointing downwards. The numbers next to the potassium atoms are their $y$ coordinates.
is 0.094 for 1017 observed reflexions. A list of structure factors is available on request.

In Table 2 the atomic coordinates, and in Table 3 the thermal parameters given by the temperature factor $\exp \left[-2 \pi^{2}\left(U_{11} a^{* 2} h^{2}+\ldots+2 U_{12} a^{*} b^{*} h k+\ldots\right)\right]$, and their respective standard deviations are listed. The atoms are labelled in accordance with Figs. 1 and 2. In order to distinguish between the angles around the central sulphur atom $\mathrm{S}(1)$, two of the oxygen atoms are primed in Fig. 2.

## Discussion of the structure

Atomic distances are listed in Table 4, bond angles in Table 5 and oxygen-oxygen distances in the $\mathrm{SO}_{4}$ groups in Table 6. The contribution of the uncertainty of the estimate of the $a$-axis to the variance of the distance is given by

$$
v_{a}=\left[a(\Delta x)^{2} / r\right]^{2} \sigma_{a}^{2}
$$

If we take $\sigma_{a}=0.013$ the correction proves to be negligible in all cases except the $S(1)-S(2)$ distance, which has been corrected in this way. The influence on the standard deviations of the angles has been estimated by calculating the angles twice, first with $a=9.19$ and then with $a=9 \cdot 19 \pm 0 \cdot 013$. The discrepancies were regarded as the error resulting from the uncertainty in the $a$ axis alone. Again the contribution to the variance proved to be negligible. The distances between K and O atoms shorter than $3.7 \AA$ are indicated in Fig. 2. Their standard deviations are all about $0.009 \AA$. The $\mathrm{K}^{+}$ions are situated close to the $b$ and $c$ glide planes,
forming layers at approximately $y=0$ and $y=\frac{1}{2}$, with the $\mathrm{S}_{5} \mathrm{O}_{16}^{2-}$ chains in between. They are surrounded by eight oxygen atoms if distances shorter than $3.7 \AA$ are considered. The largest K-O separation is $3 \cdot 10 \AA$.

The two halves of the $\mathrm{S}_{5} \mathrm{O}_{16}^{2-}$ ion are related by a twofold axis passing through the central sulphur atom. The S-O (bridge) distances are alternately short and long going from $\mathbf{S}(1)$ along the chain. The bridge angles S-O-S and O-S-O are about $123^{\circ}$ and $102^{\circ}$ respectively. The angles between the non-bridging oxygen atoms and $\mathrm{S}(1)$ and $\mathrm{S}(2)$ are about $122^{\circ}$. The $\mathrm{O}-\mathrm{O}$ and $\mathrm{S}-\mathrm{O}$ distances belonging to the $\mathrm{SO}_{4}$ groups at the ends of the anion chains indicate that the tetrahedral configuration around the terminal sulphur atoms is distorted. The sulphur atoms are shifted from the centres of the pseu-do-tetrahedra towards the three non-briding oxygen atoms, giving nearly $C_{3 v}$ symmetry at the terminal sulphur atoms. The angles between the bond $\mathrm{O}(2)-\mathrm{S}(3)$ and the bonds from $S(3)$ to $O(3), O(4)$ and $O(5)$ are about $100^{\circ}$; the dihedral angles between the planes through $O(2), S(3)$ and each of the three other oxygen atoms are about $120^{\circ}$. The $\mathrm{O}(2)-\mathrm{S}(3)$ bond is exceptionally long ( $1.83 \AA$ ), which is much geater than the assumed single bond separation of $1.69 \AA$, calculated by the Schomaker-Stevenson equation (Schomaker \& Stevenson, 1941). This indicates a large contribution of the sulphur $d_{2^{2}}$ orbital to the S-O $\sigma$-bond. Since the terminal group is almost planar it may be considered as a $\mathrm{SO}_{3}$ molecule weakly bound to the chain.
As the dihedral angle between the planes $\mathrm{O}(1)-\mathrm{S}(1)-$ $O\left(1^{\prime}\right)$ and $S(1)-O\left(1^{\prime}\right)-S(2)$ is $67^{\circ}$ the configuration around the $\mathrm{S}(1)-\mathrm{O}(1)$ bond is almost staggered. This

is not the case for the $\mathrm{S}(2)-\mathrm{O}(1)$ and the $\mathrm{S}(2)-\mathrm{O}(2)$ bonds, the corresponding dihedral angles being about $88^{\circ}$. The crystal structure of $\left(\mathrm{NO}_{2}^{+}\right)_{2} \mathrm{~S}_{3} \mathrm{O}_{10}^{2-}$ was determined by Eriks \& MacGillavry (1954) and refined by Cruickshank (1964). There are many similarities between the $\mathrm{S}_{3} \mathrm{O}_{10}^{2-}$ and the $\mathrm{S}_{5} \mathrm{O}_{16}^{2-}$ ion; the terminal groups in the two anions are almost identical. Although in the former anion the S-O bridge bond in the terminal group is $0.1 \AA$ shorter, it is also exceptionally long. Since Cruickshank's estimated standard deviations of the bond lengths are about $0.05 \AA$ the question of whether the difference might be significant can only be settled if a more accurate structure determination of a $\mathrm{S}_{3} \mathrm{O}_{10}^{2-}$ compound is carried out. At present the S-O bridge bond in the terminal group of $\mathrm{S}_{3} \mathrm{O}_{10}^{2-}$ may be regarded as intermediate between the $\mathrm{S}(3)-\mathrm{O}(2)$ and $\mathrm{S}(2)-\mathrm{O}(1)$ bond lengths in $\mathrm{S}_{5} \mathrm{O}_{16}^{2-}$. The $\mathrm{S}-\mathrm{O}$ (bridge) distance ( $1.54 \AA$ ) to the central sulphur atom in $\mathrm{S}_{3} \mathrm{O}_{10}^{2-}$ is between those of $\mathrm{S}(1)-\mathrm{O}(1)$ and $\mathrm{S}(2)-\mathrm{O}(2)$ in $\mathrm{S}_{5} \mathrm{O}_{16}^{2-}$.

The non-bridging S-O separations in $\mathrm{S}_{3} \mathrm{O}_{10}^{2}$ are $1.42 \AA$ for the end group and $1.38 \AA$ for the central
sulphur atom, and about the same distances are found in $\mathrm{S}_{5} \mathrm{O}_{16}^{2}$. The bond angles we find agree favourably with those of $\mathrm{S}_{3} \mathrm{O}_{10}^{2-}$, but the $\mathrm{O}-\mathrm{S}-\mathrm{O}$ bridge angle ( $101^{\circ}$ ) in $\mathrm{S}_{3} \mathrm{O}_{10}^{2-}$ is closer to the $\mathrm{O}(1)-\mathrm{S}(2)-\mathrm{O}(2)$ angle ( $102^{\circ}$ ) than to the central bridge angle $\left(105^{\circ}\right)$.

The authors wish to express their gratitude to Professor H. Gerding for initiating this research, Mr A. Kreuger for his skilful preparation of the photographs and Professor C.H. MacGillavry and Dr C. Romers for their advice in preparing this paper.
