# Crystal and Molecular Structure of Hexaquomagnesium Trihydrogenhexaoxoiodate(VII)

BY F. BIGOLI, A. M. MANOTTI LANFREDI, A. TIRIPICCHIO AND M. TIRIPICCHIO CAMELLINI

Istituto di Chimica Generale, University of Parma, Parma, Italy

## (Received 8 July 1969)

Crystals of hexaquomagnesium trihydrogenhexaoxoiodate(VII), [Mg(OH<sub>2</sub>)<sub>6</sub>] [H<sub>3</sub>IO<sub>6</sub>], are monoclinic, space group Pc. The unit-cell constants are a = 5.180 (6), b = 9.886 (13), c = 10.625 (7) Å,  $\beta = 116.90$  (15)°, Z=2. The structure was solved from three-dimensional data ( $R=8\cdot8\%$ ). The structure consists of octahedral cations  $[Mg(OH_2)_6]^{2+}$  and octahedral anions  $[H_3IO_6]^{2-}$ . The jodine-oxygen bond lengths range from 2.01 to 1.78 Å, and the magnesium-water bond lengths from 2.15 to 2.06 Å. The hexaquocations and the trihydrogenhexaoxoiodato(VII) anions are held together by a dense network of hydrogen bonds. There are fourteen independent possible hydrogen bonds  $0 \cdots 0$ , shorter than 2.86 Å, the shortest being 2.56 Å.

#### Introduction

As part of a programme of research on compounds of oxygenated acids of iodine(VII) and iodine(V) (Ferrari, Braibanti & Tiripicchio, 1965; Ferrari, Cingi & Guastini, 1967; Biagini Cingi, Emiliani & Guastini, 1967; Braibanti, Tiripicchio & Manotti Lanfredi, 1967) a

hydrated magnesium periodate has been examined. The compound could be represented, assuming the existence of hexaquomagnesium cations, either as an enneaoxodiiodate(VII), [Mg(OH<sub>2</sub>)<sub>6</sub>]<sub>2</sub> [I<sub>2</sub>O<sub>9</sub>].3H<sub>2</sub>O, or as a dihydrogendecaoxodiiodate(VII), [Mg(OH<sub>2</sub>)<sub>6</sub>]<sub>2</sub>  $[H_2I_2O_{10}]$ . 2H<sub>2</sub>O, or as a trihydrogenhexaoxoiodate-(VII), [Mg(OH<sub>2</sub>)<sub>6</sub>] [H<sub>3</sub>IO<sub>6</sub>]. According to Siebert (1967) the compound should be considered as a dihydrogendecaoxodiiodate(VII), an assignment based on an analysis of the infrared spectrum of the compound. On the other hand, Ferrari, Cingi & Guastini (1967) concluded, on the grounds of chromatographic tests, that the compound is very likely a trihydrogenhexaoxoiodate(VII). Therefore, the study of the crystal structure of this compound has been undertaken in order to solve the problem.

#### Experimental

#### Preparation

Crystals of the compound were obtained by evaporation of aqueous solutions, obtained from equivalent amounts of magnesium carbonate and periodic acid.

#### Crystal data

Compound: hexaquomagnesium trihydrogenhexaoxoiodate(VII), [Mg(OH<sub>2</sub>)<sub>6</sub>] [H<sub>3</sub>IO<sub>6</sub>], F.W. 358·35.

Crystal class: monoclinic, domatic.

Unit cell (Cu K $\alpha$ ,  $\bar{\lambda} = 1.5418$  Å; from rotation and

Weissenberg photographs around [100] and [010]):

a = 5.180(6), b=9.886(13), c=10.625(7) Å  $\beta$  116.90(15)°, V=485.4 Å<sup>3</sup>, Z=2

- $D_x = 2.45, D_m = 2.45 \text{ g.cm}^{-3}$

Space group:  $Pc(C_s^2, No.7)$  from systematic absences and positive piezoelectric responce.

 $\mu(Cu K\alpha) = 276.9 \text{ cm}^{-1}$ .

Table 3 (cont.)

# Intensity measurement

Integrated reflexions (831 observed out of 867 possible reflexions) h0l,  $h1l \cdots h7l$  and 0kl were obtained by a Weissenberg camera and their intensities measured by a microdensitometer. The crystal used was a pseudohexagonal elongated prism and absorption corrections were applied as for cylindrical specimens ( $\mu \overline{R}[010] = 5 \cdot 3$ ). The scattering factors were used in analytical form (Moore, 1963). No correction for anomalous dispersion was introduced because the iodine atoms were considered to be centrosymmetric with respect to each other and therefore their contributions to  $\Delta f''$  cancelled one another out.

The calculations were performed on the computer Olivetti Elea 6001/S of the Centro di Calcolo elettronico of the University of Parma.

#### Determination and refinement of the structure

The structure was solved by Patterson and Fourier methods. The Fourier syntheses showed unequivocally that the structure of this compound is derived from hexaoxoiodic(VII) acid (orthoperiodic acid) and any

other possible hypothesis can be excluded. The refinement was carried out by differential syntheses; anisotropic thermal parameters were refined by the method of Nardelli & Fava (1960) (R=8.8%, observed reflexions only). No definite physical significance can be attributed to the thermal parameters since their accuracy was highly affected by the systematic errors in the experimental data. The final results are quoted in Tables 1–5.

#### Discussion

The whole structure (Fig. 1) appears to be built up from anions  $[H_3IO_6]^{2-}$  and hexaquocations, in approximate octahedra, held together by a dense network of hydrogen bonds. The iodine-oxygen bonds are not equal, ranging from 1.78 to 2.01 Å (Fig.2). Oxygen atoms shared between I and H correspond generally to the longest iodine-oxygen bonds and unshared oxygen atoms to the shortest ones (Ferrari, Braibanti & Tiripicchio, 1965). Therefore I-O(2) = 1.78 and I-O(3) = 1.87 Å can be classified as I-O bonds and I-O(1)=2.01 Å and I-O(6)=1.97 Å as I-OH while I-O(5) = 1.95 and I-O(4) = 1.93 Å could share one hydrogen atom because they form a very strong hydrogen bond with one another  $[O(5) \cdots O(4^{i}) = 2 \cdot 56 \text{ Å}]$ . In principle the assignment of H to O(5) seems more likely because this were so the anion would be transoctahedrally coordinated (Jones, 1964) and consequently the hydrogen atoms should be as far as possible from one another.

Unfortunately the standard deviations are rather high. The angles between iodine-oxygen bonds show an average deviation  $\pm 2.3^{\circ}$  from 90° with maximum deviation  $-4.9^{\circ}$ , which suggests that the deviation from the octahedral configuration is not too high. The metal-water distances in the hexaquomagnesium cation range from 2.06 to 2.15 Å (Fig. 2). Distances quoted in the literature for this aquo cation are:  $Mg-OH_2 = 2.115$ , 2.068, 2.068 (Nardelli, Fava & Giraldi, 1962), 2.054, 2.099, 2.045, 2.046, 2.092, 2.055 (Baur, 1964), 2.054,

Fig. 1. Clinographic view of the structure.

Fig.2. Hydrogen bonds radiating from the octahedral groups  $[Mg(OH_2)_6]^{2+}$  and  $[H_3IO_6]^{2-}$ .

2.059, 2.083 and 2.044, 2.046, 2.080 (Zalkin, Ruben & Templeton, 1964), 2.081, 2.080, 2.061 (Johnson, 1965), 2.059, 2.061, 2.065 (Sasvari & Jeffrey, 1966), 2.083, 2.073, 2.051 (Margulis & Templeton, 1962), and 2.053, 2.061, 2.063 Å (Braibanti, Tiripicchio, Manotti Lanfredi & Bigoli, 1969). The angles around the magnesium atom are again approximately octahedral. The hydrogen bonds (Table 5) play an important role in the crystal structure. They are numerous and strong. There are fourteen independent possible hydrogen bonds  $O \cdots O \le 2.86$  Å (Fig. 2). An attempt has been made to distinguish between donor (of hydrogen) and acceptor atoms and a reasonable scheme consistent with the assignment of hydrogen atoms in the anion has been obtained. According to this tentative scheme two hydrogen bonds are assigned to each water molecule on the assumption that the water molecules contribute to the bond as hydrogen donors. The corresponding angles with the oxygen atoms bound through hydrogen bridges are:  $O(6^{iii}) \cdots O(7) \cdots O(5^{ii}) =$  $127 \cdot 2, O(2^{i1i}) \cdot \cdot \cdot O(\overline{8}) \cdot \cdot \cdot O(12^{i}) = 107 \cdot 7, O(3^{i}) \cdot \cdot \cdot$  $O(9) \cdots O(5^{1v}) = 104.7, O(4^{1v}) \cdots O(10) \cdots O(11^{v})$ = 100.0,  $O(3^{iv}) \cdots O(11) \cdots O(4^{vi}) = 102.9$  and  $O(1^{iii}) \cdot O(12) \cdot O(3) = 125 \cdot 6^{\circ}$ , which are reasonable values (Hamilton & Ibers, 1968). These bonds connect water molecules either with anions or with other molecules. Two more strong hydrogen bonds occur between anions  $O(2) \cdots O(6^{i}) = 2.64$  Å, with O(6) as donor, and  $O(5) \cdots O(4^{i}) = 2.56$  Å, possibly with the hydrogen atom shared between the two. Even if limited by uncertainties due to the experimental errors, these conclusions seem acceptable.

(Received 28 April 1969 and in revised form 2 October 1969)

Thiepin 1,1-dioxide,  $C_6H_6SO_2$ , crystallizes in the monoclinic space group  $P2_1/n$  with cell dimensions of a = 6.788, b = 13.173, c = 7.596 Å,  $\beta = 109.10^{\circ}$ , and four molecules per unit cell. Three-dimensional X-ray diffraction data were initially collected using a Weissenberg camera and Cu K $\alpha$  radiation; a second set was subsequently measured with Mo K $\alpha$  radiation on an automatic diffractometer. The structure was readily solved by location of the intermolecular S-S vectors in the Patterson function. Refinement was carried out by full matrix least-squares with anisotropic temperature factors to an R of 0.055 (weighted R = 0.024). Hydrogen atoms were included with isotropic temperature factors. Only the counter data were used in the final refinement cycles. There is substantial evidence for double-bond character in the two C-S bonds; no firm conclusions can be drawn regarding delocalization in the carbon atom portion of the molecule.

## Introduction

Sulfur may expand its valence shell beyond the Lewis octet by accepting ligand electrons of  $\pi$  symmetry into

its unfilled 3d orbitals. The formation of a new chemical bond between the acceptor (sulfur) and donor (ligand) will occur if (a) the necessary donor and acceptor orbitals overlap appreciably with each other and
