# The Crystal Structures of Two Oxyfluorides of Molybdenum\*

## By J.W.PIERCE<sup>†</sup> and M.VLASSE

Department of Chemistry and the Division

of Engineering, Brown University, Providence, Rhode Island 02912, U.S.A.

#### (Received 20 November 1969)

Single crystals of the compounds  $MoO_{2}\cdot 4F_{0.6}$  and  $Mo_4O_{11}\cdot 2F_{0.8}$  were prepared by reacting  $MoO_3$  and powdered Mo metal in the presence of HF under hydrothermal conditions at 500 °C and 2 kbar pressure.  $Mo_4O_{11}\cdot 2F_{0.8}$  is orthorhombic with space group *Cmcm*, Z=4, cell dimensions  $a=3\cdot878\pm0\cdot004$ ,  $b=13\cdot96\pm0\cdot01$ ,  $c=3\cdot732\pm0\cdot005$  Å. The measured and calculated densities are  $d_m=4\cdot6\pm0\cdot1$  and  $d_c=4\cdot70$  g.cm<sup>-3</sup>. The intensity data were collected by the Weissenberg method and the structure refined by least-squares to a final *R* value of  $9\cdot1\%$  for 465 independent reflections. The structure is related to the MoO<sub>3</sub> structure with the Mo atom in a very distorted octahedral coordination.  $MoO_{2}\cdot4F_{0\cdot6}$  is cubic with space group *Pm3m*, Z=1, cell dimension  $a=3\cdot842\pm0\cdot003$  Å, measured and calculated densities of  $d_m=4\cdot1\pm0\cdot1$  and  $d_c=4\cdot22$  g.cm<sup>-3</sup>. The intensities were measured by powder diffractometry and the *R* value based on intensities for 20 reflections was 12%. The structure is similar to the ReO<sub>3</sub> structure with the Mo atom in a normal octahedral coordination.

#### Introduction

Extensive studies on the structural chemistry of the molybdenum and tungsten oxide systems have been reviewed by Anderson & Magnéli (1950); Hägg & Magnéli (1954) and Kihlborg (1963). The structures of  $MoO_2$  and  $MoO_3$ , as well as those of a number of intermediate oxides, have been established. The basic building unit for these structures is a distorted  $MoO_6$  octahedron; however, the degree of distortion may be large

enough to alter significantly the number of neighbors nearest to the molybdenum atoms.

It was first suggested by Magnéli (1956) that an increase in the amount of reduced molybdenum present in the compound is accompanied by an increase in the coordination number of the molybdenum atoms. In the  $MoO_3$  structure the molybdenum atoms have a strong tendency toward fourfold coordination. However, in  $Mo_{18}O_{52}$  the average number of oxygen atom near-neighbors approaches five, and in  $Mo_4O_{11}$  the coordination number of the molybdenum atoms approaches six.

In addition, Wilhelmi (1969) has recently determined the structure of  $Mo_4O_{10}(OH)_2$  and found it to be closely related to those of  $MoO_3$  and  $Mo_{18}O_{52}$ . In the case of  $Mo_4O_{10}(OH)_2$  reduced molybdenum has been intro-

<sup>†</sup> Present address: Lincoln Laboratory, Massachusetts Institute of Technology, Lexington, Massachusetts, U.S.A.

duced into the structure while the anion to cation ratio remains 3:1. It has also been demonstrated by Sleight (1969) that compounds of the type  $MoO_{3-x}F_x$  could be prepared.

The work of Wilhelmi (1969) indicated the possible existence of additional molybdenum oxyfluoride phases with structures related to the more distorted  $MoO_3$  structure and containing smaller amounts of fluorine. Further investigation of the Mo–O–F system in this laboratory resulted in the preparation of single crystals of  $Mo_4O_{11\cdot2}F_{0\cdot8}$ .

The work described here was undertaken in order to determine the structure of  $Mo_4O_{11\cdot 2}F_{0\cdot 8}$  and to verify the relationship between the ReO<sub>3</sub> structure and that of the cubic phases reported by Sleight (1969).

#### Experimental

#### Preparation and crystal growth

In order to prepare single crystals of Mo<sub>4</sub>O<sub>11·2</sub>F<sub>0·8</sub>, mixtures of MoO<sub>3</sub> and powdered molybdenum metal were weighed-out in mole ratios between 79:1 and 29:1. One gram of the mixed powder was then placed in an ampule formed by sealing one end of a 10 cm length of 5 mm (I.D.) gold tubing. Approximately 1 cc of 48% hydrofluoric acid was then added before the open end of the tube was crimped and melted to form a tight seal. The capsule was then placed in a pressure vessel and attached to hydrothermal pressure equipment available commercially.\* The temperature, as measured with thermocouples attached to the outside of the pressure vessel, was brought rapidly to 515 °C while the pressure was held at 2 kbar. The vessel was then cooled at a rate of 5°hr<sup>-1</sup> to 500°C. The reaction was then allowed to proceed for 6 days at 500° under 2 kbar pressure before the vessel was slowly cooled to room temperature.

The same procedure was followed in the synthesis of  $MoO_{2\cdot4}F_{0\cdot6}$ ; however, the initial mole ratio of  $MoO_3$ : Mo was between 13:1 and 14:1.

## Analyses

Samples of  $Mo_4O_{11\cdot 2}F_{0\cdot 8}$  were decomposed in 2N NaOH, brought to pH 5 with 2N HCl, and diluted to 100 ml. Fluorine was then determined with a specific ion electrode.<sup>†</sup> The total molybdenum in the sample was determined by passing the solution through a silver reductor and titrating the resulting  $Mo^{5+}$  with ceric sulfate.

Samples of  $MoO_{2-4}F_{0-6}$  were decomposed in 2N HCl to which a trace of HNO<sub>3</sub> had been added. The solution was brought to pH 5 with 2N NaOH and subjected to the same fluorine and molybdenum determinations described above.

The total reducing power of both materials was determined by dissolving them in acid V<sup>5+</sup> sulfate solution and titrating the resulting V<sup>4+</sup> potentiometrically with ceric sulfate solution. The results were: calculated, for Mo<sub>4</sub>O<sub>11·2</sub>F<sub>0·8</sub>: Mo, 66·40; F, 2·37; Mo<sub>red</sub> (as Mo<sup>5+</sup>), 11·95; found: Mo, 66·0; F, 2·4; Mo<sub>red</sub>, 13·1. Calculated for MoO<sub>2·4</sub>F<sub>0·6</sub>: Mo, 65·82; F, 7·95; Mo<sub>red</sub>, 40·16, found: Mo, 65·5; F, 7·9; Mo<sub>red</sub>, 42·8.

## Structure determination of Mo<sub>4</sub>O<sub>11·2</sub>F<sub>0·8</sub>

Powdered samples were prepared from the single crystals and examined using a Norelco diffractometer with monochromatic radiation (AMR-202 focusing monochromator) and a high intensity copper source  $[\lambda(Cu K\alpha_1) = 1.5405 \text{ Å})]$ , with a focal spot size of  $1.2 \times 3$  mm for 6° take-off angle. Powder diffraction data on  $MoO_{2\cdot 8}F_{0\cdot 2}$  at 25° were indexed on the basis of an orthorhombic cell with  $a = 3.878 \pm 0.005$ , b = $13.96 \pm 0.01$ , and  $c = 3.732 \pm 0.005$  Å. In addition, lattice constants were determined from single-crystal rotation and Weissenberg photographs,  $a = 3.874 \pm 0.007$ ,  $b = 13.96 \pm 0.01$  and  $c = 3.738 \pm 0.007$  Å, using molybdenum radiation  $[\lambda(Mo K\alpha_1) = 0.70926 \text{ Å}]$  and focal spot size of  $1 \times 1$  mm. The pycnometrically measured density was  $d_m = 4.6 \pm 0.1$  g.cm<sup>-3</sup> which indicated a cell containing four  $MoO_{2\cdot 8}F_{0\cdot 2}$  units. The calculated density  $d_c = 4.70$  g.cm<sup>-3</sup>. The reported errors for both the powder and single-crystal cell parameters represent the average deviations in the observed cell constants.

The Laue symmetry was found to be *mmm*. Systematic extinctions, determined from zero- and upper-layer Weissenberg and precession photographs occurred only for hkl: h+k=2n+1 and h0l: l=2n+1. These extinctions are consistent with space groups *Cmcm*, *C2cm* and *Cmc2*<sub>1</sub>. Piezoelectric and pyroelectric measurements were not made on this material as it had been shown to be a semiconductor (Cady, 1929).

A single crystal of  $Mo_4O_{11\cdot 2}F_{0\cdot 8}$  in the form of a flattened needle was cleaved to give a sample approximately  $0.1 \times 0.1 \times 0.3$  mm. This was mounted about its c axis and data were taken for l=0-6, using the multiple-film equi-inclination Weissenberg technique with Zr-filtered Mo radiation. The sample was then cut and remounted about its a axis and data were taken for h=0-6. A total of 980 reflections were measured visually by comparison with a standard intensity scale. These data were scaled and average to give a total of 465 independent reflections. Corrections were applied to the data for extended spot-shape and Lorentz-polarization effects. The inter-film and interlayer scaling was carried out by the usual scaling algorithms (Hamilton, Rollett & Sparks, 1965). No absorption or extinction corrections were applied. Before the averaging of equivalent reflections was made, lack of absorption correction caused an estimated maximum error of 10% in the intensities of some reflections.

Comparison of the powder patterns of  $MoO_3$  and  $Mo_4O_{11\cdot 2}F_{0\cdot 8}$  indicated that the two structures were

<sup>\*</sup> A model HR-2C-2 hydrothermal bench was used in conjunction with modified LRA-150 pressure vessels. Tem-Pres Research Inc., State College, Pennsylvania.

closely related. In the three possible space groups the molybdenum, oxygen and fluorine atoms occupy positions 4(b) in C2cm, 4(c) in Cmcm, or 4(a) in Cmc2<sub>1</sub>. These positions are analogous to the corresponding positions in the MoO<sub>3</sub> structure. The initial positional parameters for the refinement were assumed to be

those observed for  $MoO_3$  and shown in Table 1. It was assumed that the oxygen and fluorine atoms were randomly distributed among the three sets of oxygen positions. The refinement was carried out using a full-matrix least-squares algorithm (Busing, Martin & Levy, 1962), modified to make real and imaginary

anomalous dispersion corrections. The atomic scattering factors for oxygen, fluorine and molybdenum were taken from *International Tables for X-ray Crystallography* (1962). The necessary parameters used for the anomalous dispersion were those given by Dauben & Templeton (1962). Weights were assigned to each reflection according to the scheme of Cruickshank & Pilling (1961), *i.e.*  $w = (A + BF_o + CF_o^2)^{-1}$ , with A = $2F_{\min}$ , B = 1.0, and  $C = 2/F_{\max}$  ( $F_{\max} = 410$ ,  $F_{\min} = 25$ ).

The function  $\sum w(|F_o| - |F_c|)^2$  was minimized where  $F_o$  and  $F_c$  are the observed and calculated structure amplitudes and w is the weight defined above. For the refinement procedure one overall scale factor was used. Initially the refinement was carried out in the non-centrosymmetric space group, C2cm. In the course of several cycles of isotropic refinement in the non-centrosymmetric space group, the x parameters of all the atoms were observed to oscillate across a mirror plane consistent with the centrosymmetric space group Cmcm.

It was then decided to refine the structure in the centrosymmetric space group. Three cycles of isotropic least-squares refinement led to the following R indices:

$$R = \frac{\sum ||F_o| - |F_c||}{\sum |F_o|} = 0.119$$
$$wR = \left[\frac{\sum w (|F_o| - |F_c|)^2}{\sum w |F_o|^2}\right]^{1/2} = 0.133.$$

The refinement was then continued with several anisotropic calculations. The final values of R and wR were 0.091 and 0.117 respectively. The final positional and thermal parameters of this refinement are given in Table 1. Interatomic distances, bond angles, and the standard deviations of these parameters were calculated using the Busing, Martin & Levy (1964) ORFFE program and are shown in Table 2. The final structure factors are given in Table 3 for observed reflections only. Those reflections too weak to observe had, at the end, calculated structure factors whose magnitude did not exceed the minimum observable value in nearby regions of reciprocal space.

Fig. 1. The structure of  $Mo_4O_{11\cdot 2}F_{0\cdot 8}$  showing layers of distorted  $MoX_6$  octahedra sharing edges and corners.

Structure determination of MoO<sub>2·4</sub>F<sub>0·6</sub>

Powder diffraction patterns and single-crystal precession photographs indicated that this phase was cubic with a cell constant  $a=3.842\pm0.003$  Å. The pycnometrically determined density was  $d_m=4.1\pm0.1$  g.cm<sup>-3</sup> indicating a cell containing one formula unit. The calculated density was  $d_c=4.22$  g.cm<sup>-3</sup>.

The Laue symmetry was found to be m3m. No systematic extinctions were observed. Three space groups are therefore possible: P432,  $P\overline{4}3m$ , and Pm3m. The space group Pm3m was assumed for this material. This space group is consistent with that assigned to the ReO<sub>3</sub> structure.

A powdered sample was mixed with Canada balsam in order to alleviate preferred orientation effects and integrated intensity data were collected with a Norelco diffractometer.

Parthé's<sup>\*</sup> program was used to calculate intensities based on the ReO<sub>3</sub> structure with oxygen and fluorine atoms distributed randomly in the positions 3(d),  $(\frac{1}{2}00)$ , and the molybdenum atom at position 1(a), (000), of space group *Pm3m*. The occupancy factors for oxygen and fluorine were adjusted to comply with the observed stoichiometry. The isotropic temperature factor was set at 1.00 based on temperature factors observed for other molybdenum oxides. The data were corrected for Lorentz-polarization effects. The results are shown in Table 4. The reliability index based on intensity was found to be:

$$R_{I_o} = \frac{\sum |I_o - I_c|}{\sum |I_o|} = 0.12.$$

## **Results and discussion**

The structure of  $Mo_4O_{11}$ ,  $2F_{0.8}$  is similar to that of the parent oxide  $MoO_3$  (Kihlborg, 1963) and isostructural

<sup>\*</sup> W. Jeitschko & E. Parthé, A Fortran IV Program for the Intensity Calculation of Powder Patterns. Univ of Pennsylvania Press.

with  $Mo_4O_{10}(OH)_2$  (Wilhelmi, 1969). All three structures are composed of distorted  $MoX_6$  octahedra linked as shown in Fig. 1. The octahedra are joined by edges to form zigzag-shaped rows which are mutually connected by corners to form layers. The layers are placed side by side so that adjacent layers have no atoms in common. In this way three of the six anions surrounding each molybdenum atom are common to three  $MoX_6$  octahedra and two of them are shared by two octahedra. The sixth anion is unshared and Wilhelmi (1969) asserts on the basis of observed bond lengths that hydrogen bonds between pairs of these anions in adjacent layers account for the observed stoichiometry of  $Mo_4O_{10}(OH)_2$ .

Fig. 2 shows the structure viewed down the c axis and illustrates the major difference batween the structure of MoO<sub>3</sub> [Fig. (2a)] and the structures of Mo<sub>4</sub>O<sub>10</sub>(OH)<sub>2</sub> and Mo<sub>4</sub>O<sub>11·2</sub>F<sub>0·8</sub> [Fig. (2b)]. Fig. 3(a), (b) and (c) illustrates the coordination of anions about the molybdenum atoms for MoO<sub>3</sub>, Mo<sub>4</sub>O<sub>10</sub>(OH)<sub>2</sub> and

Fig. 2. The crystal structure of (a)  $MoO_3$  and (b)  $Mo_4O_{11\cdot 2}F_{0\cdot 8}$ in terms of octahedra. Heavy lines indicate the octahedra above, and light lines octahedra below. The black dot indicates the position of the molybdenum atom in the octahedra.

 $Mo_4O_{11\cdot 2}F_{0\cdot 8}$  respectively. Interatomic distances are presented for comparison in Table 5.

Kihlborg (1963) has shown that  $MoO_3$  represents a transitional stage between octahedral and tetrahedral coordination with a strong tendency toward fourfold coordination. In the structure common to  $Mo_4O_{10}(OH)_2$  and  $Mo_4O_{11\cdot 2}F_{0\cdot 8}$  the tendency towards a more ideal octahedral coordination around the molybdenum atoms is obvious.

The structure of the cubic phase,  $MoO_{2\cdot4}F_{0\cdot6}$ , consists of a three-dimensional array of regular  $MoX_6$  octahedra joined by sharing corners as shown in Fig. 4. In this case octahedral coordination has been attained.

It can be seen from Table 6 that the structures of the oxyfluorides are consistent with the predictions of Magnéli (1956), namely that as the amount of reduced molybdenum in the compound increases, the coordination number of molybdenum approaches a maximum.

Table 6. Formal oxidation state and coordination
number of molybdenum in compounds with
stoichiometries approaching MoX <sub>2</sub>

Compound	Oxidation State	Coordina- tion No.
MoO <sub>3</sub>	6.00	4
$Mo_4O_{11\cdot 2}F_{0\cdot 8}$	5.80	5
M018O52	5.78	5
Mo <sub>4</sub> O <sub>11</sub>	5.50	6
MoO <sub>2·4</sub> F <sub>0·6</sub>	5.40	6

# X-ray Crystallography of the Diphosphatriazines. I. The Crystal of Structure of 6-Methyl-2,2,4,4-tetraphenyldiphospha-1,3,5-triazine

## By F. R. Ahmed and D. R. Pollard\*

Biochemistry Laboratory, National Research Council of Canada, Ottawa 7, Canada

## (Received 6 March 1970)

The crystal structure of 6-methyl-2,2,4,4-tetraphenyldiphospha-1,3,5-triazine has been determined from Patterson and Fourier syntheses, and has been refined by least-squares to an *R* index of 0.067 for 4832 observed reflexions. The unit cell is triclinic,  $P\bar{1}$ , of dimensions a=13.585, b=18.007, c=10.838 Å,  $\alpha=79.42$ ,  $\beta=112.97$ ,  $\gamma=109.58^{\circ}$ , and has two molecules in the asymmetric unit. The diphosphatriazine ring is non-planar, has a skewed boat form and approximate twofold symmetry, and its atoms are within -0.07 and +0.10 Å from the mean plane. The weighted mean bond lengths are: P-N in P-N-P segments, 1.597; P-N in P-N-C segments, 1.620; P-C, 1.801; N-C, 1.335; C-CH<sub>3</sub>, 1.508 Å. The weighted mean angles are: N-P-N, 116.5; P-N-P, 115.4; P-N-C, 119.9; N-C-N, 129.1; C-P-C, 105.4; N-C-CH<sub>3</sub>, 115.4^{\circ}. One of the phenyl rings is disordered and has two possible orientations.

#### Introduction

The six-membered diphosphatriazine ring,  $CP_2N_3$ , is intermediate between the aromatic and planar triazine ring,  $C_3N_3$ , and the cyclotriphosphazene ring,  $P_3N_3$ , which has been found to be planar only in  $F_6P_3N_3$  and non-planar in other compounds by varying amounts depending on the ligands. In order to examine the planarity of the  $CP_2N_3$  ring, its bond lengths and valency angles and their dependence on the ligands, two compounds have been chosen for X-ray analysis, namely: (I) the 6-methyl-, and (II) the 6-dimethyl-
