# The Crystal and Molecular Structure of cis-trans-cis-Cyclodeca-2,4,8-triene-1,6-dione* 

By Olga Kennard $\dagger$, D.L. Wampler, J. C. Coppola, W.D.S. Motherwell and D. G. Watson University Chemical Laboratory, Cambridge, England<br>and Allen C. Larson<br>University of California, Los Alamos Scientific Laboratory, Los Alamos, New Mexico, U.S.A.

(Received 6 August 1970)

#### Abstract

The crystal and molecular structure of cis-trans-cis-cyclodeca-2,4,8-triene-1,6-dione was determined by X-ray diffraction. The crystals are triclinic, $P \bar{I}, a=5.641, b=12.025, c=6.326 \AA, \alpha=80.29^{\circ}, \beta=87.93^{\circ}$ and $\gamma=80 \cdot 40^{\circ}$. There are two molecules in the unit cell. Diffractometer data were used and the structure was refined anisotropically to $R=5 \cdot 2 \%$. The analysis showed considerable distortion about the trans double bond.

## Introduction

Cyclodeca-2,4,8-triene-1,6-dione [(I) or (II)], recently synthesized by Mulligan \& Sondheimer (1967), is a compound of considerable interest, since it is the diketo tautomer of 1,6-dihydroxy[10]annulene [e.g. (III)].

(I)

(II)

(III)

Unfortunately, it was not possible to determine by chemical methods whether the substance possesses the cis, trans, cis configuration (I) or the all-cis configuration (II). However, a three-dimensional X-ray diffraction analysis has now been carried out, and it has been found that the compound in fact is the cis, trans, cis stereoisomer (I). The analysis also afforded an opportunity of examining the precise geometry of the trans double bond in a ten-membered ring system.

## Crystal data

cis-trans-cis-Cyclodeca-2,4,8-triene-1,6-dione.
$\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{O}_{2}$; F.W. $162 \cdot 2$; m.p. $80-81^{\circ} \mathrm{C}$. Light brown, very rough plates. Triclinic, $a=5.641$ (10); $b=12.025$ (20); $c=6.326(10) ~ \AA ; \quad \alpha=80.29(5)^{\circ} ; \quad \beta=87.93(5)^{\circ}$, $\gamma=80 \cdot 40(5)^{\circ} ; V=417 \cdot 0 \AA^{3} ; Z=2 ; D$ (calc) $=1 \cdot 27 \mathrm{~g} . \mathrm{cm}^{-3}$. $\left|F_{000}\right|=172$. Space group $P \overline{1}$ from statistical distribution of $E$ 's and from the solved structure. The particular choice of the cell constants was experimentally convenient and is not the conventional reduced cell.

[^0]
## Experimental

Crystals of cis-trans-cis-cyclodeca-2,4,8-triene-1,6dione are moderately stable in air but decay rapidly in the X-ray beam to a dark brown powder. The rate of decay in the beam was reduced by mounting the crystals in capillaries which were sealed after being flushed with helium. Even with this precaution, however, it was necessary to use five crystals (typical size $0.6 \times 0.4 \times 0.2 \mathrm{~mm}$ ) to collect a full set of intensity measurements. The data from the various crystals were scaled to give a consistency of $R=3.8 \%$ for $\left|F_{o}\right|$ for the 366 equivalent reflexions measured more than once.
The intensity data and unit-cell parameters were measured with a Picker 4 -circle diffractometer using Ni -filtered $\mathrm{Cu} K \alpha$ radiation. The cell-parameters were obtained from the diffractometer settings for a number of reflections. Intensity data were collected for 1508 independent reflections in the range $0<2 \theta<136 \cdot 5^{\circ}$ using the $\theta-2 \theta$ scan mode. The $2 \theta$ scan range was $\pm 1 \cdot 6^{\circ}$; the scan rate $1 \% / \mathrm{min}$. There were 1386 reflexions with $I>2 \sigma(I)$. The data were corrected for polarization and geometrical factors.

## Solution and refinement of the structure

The structure was solved by the use of direct, mathematical methods. The phases of a small group of reflexions were derived independently, both by the sym-bolic-addition procedure (Karle \& Karle, 1966), and by the use of the tangent formula (Karle \& Karle, 1968, 1969). The structure was solved from Karle maps ( $E$ maps) based on these phases.

The calculations were carried out on an IBM 360/44 computer in Cambridge and a CDC 6600 at Los Alamos. The two approaches were tried in parallel. For each, several false starts were made, leading to Karle maps which could not be interpreted.

The symbolic-addition program assigns symbolic signs to the phases of the first terms in a list of $E$ 's ar-
ranged in descending order of magnitude. The program then proceeds to examine the $\sum_{2}$ relationships involving these reflexions and assigns the appropriate combination of symbolic signs to additional reflexions if the triple-products are equal to or greater than a preset value. The next member of the list of $E$ 's is assigned and the $\Sigma_{2}$ relationships involving this reflexions are examined. The procedure is repeated until, in the list, a minimum $E$ of about 2.0 is reached. At this stage all $E$ 's above this minimum have been given symbolic signs. Reflexions with symbolic sign-combinations are next examined and some of the symbols may be eliminated when the triple-products involved meet a certain, predetermined criterion.

When the above procedure was applied to cis-trans-cis-cyclodeca-2,4,8-triene-1,6-dione, combinations of 26 symbols were assigned to the 137 reflexions with $|E|>2 \cdot 0$. Symbols were eliminated on the criterion that the sign relationships involved had a probability $>0.98$, and various Karle maps were prepared by using permutations of the remaining phase. None of the maps could be interpreted. When the probability criterion was raised to $>0.999$, 18 symbols were eliminated by being found to be equivalent to combinations of the eight remaining symbols or to ( + ). Of the remaining eight symbols three were used to determine the origin and two could be disregarded since they were involved with two reflexions only. The three undetermined symbols gave eight permutations of 0 and $\pi$ values. Karle maps were computed for all but the all-positive set, and one of the maps led to peak positions which could be interpreted as chemically meaningful.

An alternative approach to the solution of the phase problem is the application of the tangent formula of Karle \& Karle $(1968,1969)$ to a starting set of either 6 or 7 reflexions with 'known' phases which are then used to generate phases of additional reflexions. The generated phases are expanded and refined by repeated cyclic application of the tangent formula until a consistent set is obtained. Phases from this set are used to calculate a Karle map.

To facilitate examination of these maps we have used a technique whereby the values at the grid point are printed out in a condensed format, with each section on one sheet of paper only. The map is also stored on magnetic tape which is searched for the highest peaks. Interatomic distances between a specified number of these peaks are calculated and listed. The structure can usually be examined by using this information without need for replotting any maps by hand.

For cis-trans-cis-cyclodeca-2,4,8-triene-1,6-dione a starting set of six phases was used, three of which were origin determining (Table 1). Seven phase sets were generated for the possible sign combinations of the remaining three reflexions and some of the corresponding Karle maps were computed. None of the maps could be interpreted.

As the next stage in the application of the tangent formula method, 4 non-origin defining reflexions were

Table 1. Starting phases to compute a correct phase set or cis-trans-cis-cyclodeca-2,4,8-triene-1,6-dione by use of the tangent formula

| Reflexion |  |  |  |  |  |  |  |  | $E$ | Phase |  |  |

| 2 | 4 | 4 | 3.38 | 0 | $c$ | phases |  |  |  |  |  |  |
| 2 | 8 | 0 | 2.81 | $\pi$ | $d$ |  |  |  |  |  |  |  |

selected (Table 1) and 15 phase sets generated. The program calculated various criteria for these sets including the so called $R_{\text {Karle }}$ value

$$
\frac{\sum\left|\left|E_{\mathrm{h}}\right|-\left|E_{\mathrm{h}}\right| \text { calc }\right|}{\sum\left|E_{\mathrm{h}}\right|},
$$

the average value of $\alpha=\left|E_{\mathrm{h}}\right|\left(A^{2}+B^{2}\right)^{1 / 2}$, where

$$
\begin{aligned}
& A=\sum_{\mathbf{k}}\left|E_{\mathbf{k}}\right|\left|E_{\mathrm{h}-\mathbf{k}}\right| \cos \left(\varphi_{\mathbf{k}}+\varphi_{\mathrm{h}-\mathrm{k}}\right) \\
& B=\sum_{\mathbf{k}}\left|E_{\mathbf{k}}\right|\left|E_{\mathrm{b}-\mathbf{k}}\right| \sin \left(\varphi_{\mathbf{k}}+\varphi_{\mathrm{h}-\mathrm{k}}\right),
\end{aligned}
$$

the average consistency

$$
t=\sum_{\mathbf{k}}^{\left(A^{2}+B^{2}\right)^{1 / 2}}\left|E_{\mathbf{k}}\right|\left|E_{\mathbf{h}-\mathbf{k}}\right|
$$

(taking the average over all the input reflexions $E_{\mathrm{h}}$ ), and

$$
R_{\text {Drew }}=\frac{\sum_{\mathbf{h}}\left|E_{\mathrm{h}}\right|\left(1-t_{\mathrm{h}}\right)}{\sum_{\mathrm{h}}\left|E_{\mathrm{h}}\right|}
$$

The set with the lowest $R_{\text {Karle }}$ value gave a map from which the entire structure, other than the hydrogen atoms was cvident. It is our impression from this and other structures we have recently determined that the $R_{\text {Karle }}$ value is the most sensitive indication of the correctness of a phase set.

In the calculations which led to a successful solution, a phase was accepted as determined if $\alpha>10.0(0.983$ probability). The refinement of phases converged after 20 cycles with 279 of the 281 phases for reflexions with $|E|>1.306$ being determined. The lowest $R_{\text {Karle }}$ value was 0.19 with an average value of $\alpha=201$.

The positions of all atoms other than hydrogen atoms were located from the properly phased Karle map. The maximum shift in peak position after refinement was $0 \cdot 18 \AA$ for oxygen atom $\mathrm{O}(11)$. There were some spurious peaks on the map but these were about half as high as peaks corresponding to the carbon and oxygen positions. Distances and angles between the latter peaks were chemically reasonable.

The parameters derived from the Karle map were refined, first isotropically and then anisotropically, by full-matrix least-squares calculations. On convergence
a difference-Fourier synthesis was calculated and the coordinates of the hydrogen atoms were located. Refinement was continued with anisotropic thermal parameters for the carbon and oxygen and isotropic thermal parameters for the hydrogen atoms. The refinement results are summarized in Table 2.

Table 2. Summary of refinement of cis-trans-cis-cyclodeca-2,4,8-triene-1,6-dione

| Step | $R$ |
| :---: | :---: |
| 1. Structure factor calculation using positions | $34 \cdot 0 \%$ |

from correctly phased Karle map.
2. Two cycles of isotropic least-squares refinement $\quad 18.7 \%$ of C and O positions, using 1385 terms.
3. Two cycles of anisotropic least-squares with $14 \cdot 6 \%$ C and O .
4. Hydrogen atoms from Fourier included. $\quad 13 \cdot 1 \%$
5. Four cycles, C and O anisotropic, and H isotropic $5.2 \%$

The following form factors were used: for C and H , Table 3•3•1A, International Tables for $X$-ray Crystallography (1962); for O, values from Cromer \& Mann (1968). Corrections for extinction were included in the refinement by use of Larson's (1970) equation (22), by which the calculated structure factor is given by

$$
F_{c}^{*}=K\left|F_{c}\right|\left(1+2 r^{*}\left|F_{c}\right|^{2}\left(1+\cos ^{4} 2 \theta\right) /\left(1+\cos ^{2} 2 \theta\right)\right)^{-1 / 4}
$$

where $F_{c}$ is given by the usual structure-factor equation. The final extinction parameter $r^{*}$ was $1.96(34) \times 10^{-5}$. Weights were assigned to individual reflections on the basis of counting statistics. Reflexions with $I<2 \sigma$ were treated as 'less thans' and were not used in the refinement. The final $R=\sum| | F_{o}\left|-\left|F_{c}^{*}\right| / / \Sigma F_{o}\right.$ was $5 \cdot 2 \%$. The final weighted $R$ was $2.8 \%$. The final atomic positions are listed in Table 3, the thermal parameters in Table 4 and the observed and calculated structure factors in Table 5.

| $\mathrm{H}(21)$ | $0.137(3)$ | $0.339(1)$ | $1.014(3)$ |
| $\mathrm{H}(22)$ | $0.261(3)$ | $0.445(1)$ | $1.051(3)$ |

The least-squares refinement, Fourier map calculations, and distance and angle calculations were made by using updated versions of programs by Larson, Cromer \& Roof (1964, 1965). Programs by Larson (1969) were used in making the symbolic-addition calculations, and a program originally written by Drew (1967) and extensively modified by Larson \& Motherwell (1968) was used in performing the tangent-formula calculations. A program written by Coppola \& Fawcett (1968) was used for the data reduction.

## Molecular geometry and description of structure

The analysis has established the conformation of the molecule as cis-trans-cis-cyclodeca-2,4,8-triene-1,6-di-

Table 5. Table of observed and calculated structure factors
Columns are $k, 10 F_{o} / K, 10\left|F_{c}^{*}\right|$ and $100 w^{1 / 2} . K=28.71$ (7). Negative $F_{o}$ indicates $I<2 \sigma(I)$

one. Perspective views of the structure are shown in Fig. 1 , together with the torsion angles for the $\mathrm{C}-\mathrm{C}$ conds. Individual bond distances and angles are given in Fig. 2. Standard deviations of the bond lengths are $\sigma(\mathrm{C}-\mathrm{C})=$ $0.002, \sigma(\mathrm{C}-\mathrm{O})=0.002$, and $\sigma(\mathrm{C}-\mathrm{H})=0.02 \AA$, and of the angles, $\sigma(\mathrm{C}-\mathrm{C}-\mathrm{C})=0 \cdot 2^{\circ}, \sigma(\mathrm{C}-\mathrm{C}-\mathrm{O})=0 \cdot 2^{\circ}, \sigma(\mathrm{C}-\mathrm{C}-\mathrm{H})$ $=1 \cdot 0^{\circ}$, and $\sigma(\mathrm{H}-\mathrm{C}-\mathrm{H})=1 \cdot 4^{\circ}$.

The carbon ring-skeleton can be thought of as an extreme distortion of the stable cyclodecane conformation with $C(2)$ and $C(7)$ as type I atoms (Dunitz \& Ibers, 1968) (Fig. 3). This distortion is necessitated by the steric requirement about the three double bonds. The torsion angles (Fig. 1) are approximately symmetri-
cal about a twofold axis passing through the midpoints of bonds $C(2)-C(3)$ and $C(7)-C(8)$. There is, however no indication that the carbon skeleton has a mirror symmetry as in cyclodecane (Dunitz \& Ibers, 1968) and in all-cis-1,6-dichlorodeca-1,3,6,8-tetraene (Kennard, Watson, Fawcett \& Kerr, 1971).

Of the three double-bonds, the greatest deviation from planarity occurs about the trans double C(4)-C(5) bond with a torsion angle of $160^{\circ}$, This is consistent with chemical observations that trans double bonds in medium-ring olefins are subject to considerable steric strain (Prelog, Schenker \& Gunthardt, 1952; Prelog, Schenker \& Kung, 1953; Aebi, Barton \& Lindsey, 1953.

Fig. 1. (a) Stereo drawing of the molecular structure of cis-trans-cis-cyclodeca-2,4,8-triene-1,6-dione. (b) Perspective view of cis-trans-cis-cyclodeca-2,4,8-triene-1,6-dione showing the torsion angles and numbering scheme.

Other X-ray diffraction studies (McClure, Sim, Coggon \& McPhail, 1970; Canis \& Dunitz, 1967; Rogers \& Smart, 1969) have shown deviations from planarity

Fig. 2. (a) Chemical formula for cis-trans-cis-cyclodeca-2,4,8-triene-1,6-dione showing bond distances in $\AA$ units. (b) Bond angles for cis-trans-cis-cyclodeca-2,4,-8-triene-1,6-dione. Bond angles involving hydrogen atoms are given to the nearest degree.

Fig. 3. Energetically favoured conformation of cyclodecane showing atom types. From Dunitz \& Ibers (1968).
about trans double bonds in ten-membered ring olefins complexed to $\mathrm{Ag}(\mathrm{I})$. However, to our knowledge, results reported here represent the first observations, by X-ray diffraction studies, of distortion about a trans double bond in a non-complexed ten-membered ring olefin.

In the ten-membered systems recorded in the literature the largest deviation from planarity, a torsion angle of $138^{\circ}$, was found by Dunitz (1968) and by Canis \& Dunitz (1967) in trans-cyclodecane. In discussing his result Dunitz pointed out that most of the distortion of torsion angles about trans double bonds is likely to be due to out-of-plane bending rather than pure twisting about the double bonds. He reports that a rough calculation based on ethylene force-constants suggest that a $40^{\circ}$ distortion in the torsion angle is most favourably achieved by a pure twist of $15^{\circ}$ and out-of-plane bending of $25^{\circ}$.

The presence of trisubstituted trans double bonds in the ten-membered ring olefin, pregeigerene, has allowed McClure et al. (1970) to make an experimental determination of the individual contributions of twisting and out-of-plane bending of the distortion of the torsion from $180^{\circ}$. Their results show that the $30^{\circ}$ distortion in the torsion angle about one of the double bonds is due to $10^{\circ}$ of pure twisting about the bond and $20^{\circ}$ of out-of-plane bending at the trigonal carbon atom

In our determination of the structure of cis-trans-cis-cyclodeca-2,4,8-triene-1,6-dione we have been able to locate the individual hydrogen positions and thus obtain an estimate of the relative contributions of the twisting and out-of-plane bending of the $20^{\circ}$ distortion observed about the trans double bond.

A value of about $7^{\circ}$ for the twist component is obtained by averaging the torsion angle $\mathrm{H}(15)-\mathrm{C}(4)-\mathrm{C}(5)-$ $\mathrm{C}(6)\left(8^{\circ}\right)$ and the torsion angle $\mathrm{C}(3)-\mathrm{C}(4)-\mathrm{C}(5)-\mathrm{H}(16)$ $\left(6^{\circ}\right)$. The out-of-plane bending is found to be about $13^{\circ}$ by averaging the angle of $14^{\circ}$ between the planes through atoms $C(4), C(5), C(6)$ and $C(4), C(5), H(16)$ and the angle $12^{\circ}$ between planes $\mathrm{C}(3), \mathrm{C}(4), \mathrm{C}(5)$ and $\mathrm{H}(15)$, $\mathrm{C}(4), \mathrm{C}(5)$ (Fig. 1). This proportion of about $7^{\circ}$ of pure twisting about the $C(4)-C(5)$ trans double bond and about $13^{\circ}$ out-of-plane bending around $C(4)$ and $C(5)$ is about the same as for pregeigerene and as predicted by Dunitz for trans-cyclodecane.

The deviation from planarity about the trans double bond is smaller in polyolefins than in trans-cyclodecane. This is probably due to the presence of fewer hydrogen atoms and the resultant reduction of strain introduced by transannular $\mathrm{H}-\mathrm{H}$ interactions.

In cis-trans-cis-cyclodeca-2,4,8-triene-1,6-dione, the shortest intraannular $\mathrm{H}-\mathrm{H}$ distance is $2.80 \AA$ between $H(16)$ and $H(21)$, which is considerably larger than the calculated $\mathrm{H}-\mathrm{H}$ distance of $1.97 \AA$ in trans-cyclodecane (McClure et al., 1970). The smaller amount of $\mathrm{H}-\mathrm{H}$ interaction allows shorter transannular $\mathrm{C}-\mathrm{C}$ interactions than in cyclodecane. The $C(5)-C(8)$ and $C(5)-C(9)$ intramolecular distances of $2.93 \AA$ and $3.12 \AA$ indicate possible transannular double-bond interaction. Table

6 gives a variety of transannular intramolecular distances.

Table 6. Some intramolecular distances for cis-trans-cis-cyclodeca-2,4,8-triene-1,6-dione

As expected, the distortion about the cis-double bonds in cis-trans-cis-cyclodeca-2,4,8-triene-1,6-dione is small. The four carbon atoms about each cis-double bond are coplanar within $0.009 \AA$ (root mean square of the distances of the four atoms from the best plane defined by the atoms). The most significant distortion about the cis-double bonds is the deviation by $8^{\circ}$ of $\mathrm{H}(13)$ from the plane of $\mathrm{C}(1)-\mathrm{C}(2)-\mathrm{C}(3)$ : it is below the plane as seen in Fig. 1. This value is significant since it is about five times the expected standard deviation. The explanation of this bending is not obvious,
but perhaps it is a distortion to reduce the $\mathrm{C}(2)-\mathrm{C}(3)-$ $\mathrm{C}(4)-\mathrm{C}(5)$ torsion angle to facilitate conjugation of the $\mathrm{C}(2)-\mathrm{C}(3)$ and $\mathrm{C}(4)-\mathrm{C}(5)$ double bonds. The C(3)-C(4) bond length of $1.451 \pm 0.004 \AA$ is significantly shorter than the expected single-bond value. This shortening indicates that conjugation does occur although the torsion angle about this bond $39^{\circ}$.

The packing of the cis-trans-cis-cyclodeca-2,4,8-tri-ene-1,6-dione in the crystal is illustrated in Fig. 4. The molecules are held together in the lattice by van der Waals forces only, and examination of the intermolecular contacts showed no unusually close distances.

We thank Professor Sondheimer and Dr P. J. Mulligan for suggesting the problem and providing us with the crystals used in the analysis. The work in Cambridge was supported by the Medical Research Council and the Office for Scientific and Technical Information.

We thank John Wiley \& Sons for permission to reproduce Fig. 3.

# The Crystal Structure of a 1:1 Nicotine-Salicylic Acid Complex (Nicotinyl Salicylate) 

By H.S. Kim and G. A. Jeffrey<br>Department of Crystallography, University of Pittsburgh, Pittsburgh, Pa. 15213, U.S.A.

(Received 6 July 1970)

#### Abstract

Crystals of the $1: 1$ complex of nicotine-salicylic acid, $\mathrm{C}_{10} \mathrm{~N}_{2} \mathrm{H}_{14} . \mathrm{C}_{7} \mathrm{H}_{6} \mathrm{O}_{3}$, are monoclinic, space group $P 2_{1}$, with two formula units in a unit cell, $a=7 \cdot 673$ (2), $b=11 \cdot 355$ (6), $c=9 \cdot 580$ (2) $\AA, \beta=109 \cdot 34$ (8) ${ }^{\circ}$, $D_{m}=1.270 \mathrm{~g} . \mathrm{cm}^{-3}$ at $20^{\circ} \mathrm{C}$. The structure was solved by direct methods using tangent formula phase refinement from 1411 intensities measured with $\mathrm{Cu} K \alpha$ radiation on a FACS I automatic diffractometer. The parameters were refined anisotropically to a final $R$ of 0.053 . All hydrogen atoms were located on difference synthesis. The quaternary ammonium cation of the nicotine forms a molecular complex with a salicylate anion through a $\stackrel{+}{\mathrm{N}}(\mathrm{H}) \ldots \mathrm{O}^{-}$hydrogen-bond of $2.627 \AA$. The conformational angle between the best planes of the puckered pyrrolidine and planar pyridine ring of the nicotinyl ion is $77^{\circ}$. In the salicylate anion, the carboxylate group is slightly out of the plane of the ring, by $0 \cdot 1 \AA$. As in the free acid, the hydroxyl forms a strong internal hydrogen-bond with a carboxyl oxygen, with a $\mathrm{O}(-\mathrm{H}) \ldots \mathrm{O}$ distance of $2 \cdot 544 \AA$.

## Introduction

The poisonous alkaloid, nicotine, was first isolated from tobacco by Posselt \& Reimann (1828). It is a colorless oily liquid, boiling under atmospheric pressure at $246^{\circ} \mathrm{C}$, is levorotatory, soluble in water, and oxidizes in contact with air. The formula (I), $\alpha$-pyridyl- $N$-methyl-pyrrolidine, was proposed by Pinner (1893), and confirmed by syntheses (Pictet \& Crepieux, 1895; Späth \& Bretschneider, 1928).

The parent compound has not been studied in the solid state, but crystal structures have been reported for nicotinic acid (II), and nicotinamide (III) (Wright \& King, 1953, 1954), familiarly known as the vitamin niacin.

(I)

(II)

(III)

The crystalline complex of nicotine with salicylic acid provides both a means for a structural study of this important molecule and for examining the way in which it can form a hydrogen-bonded complex with an organic acid. As such, this investigation forms part of a general study of hydrogen-bonded complexes, which has included glucose-urea (Snyder \& Rosenstein, 1971) and glucitol-pyridine (Kim, Jeffrey \& Rosenstein, 1971).

The physiological action of nicotine and chemically related compounds has, not surprisingly, been the subject of research for nearly a century. In 1951, Taylor proposed that the quaternary ammonium cation is the active molecular species at body $p \mathrm{H}$; this is supported by the fact that the monomethiodide has comparable activity (Barlow \& Dobson, 1955; Gillis \& Lewis, 1956). It also seems likely that it is this cation which occurs naturally in the tobacco plant in combination with maleic and citric acids. This work has confirmed that the salicylic acid complex is, in fact, a molecular crystal of nicotinyl salicylate (IV).
