The Crystal and Molecular Structure of Epi-inositol

BY G.A. JEFFREY AND H.S. KIM

Department of Crystallography, University of Pittsburgh, Pittsburgh, Pa. 15213, U.S.A.

(Received 22 October 1970)

The crystal structure of epi-inositol, $C_6H_{12}O_6$, has been determined from Cu K α data obtained with a FACS I automatic diffractometer. The space group is $P2_1/c$, with 4 molecules in the cell with a=4.841 (3), b=14.727 (4), c=11.236 (4) Å, $\beta=115.85^{\circ}$, $D_m=1.662$, $D_x=1.660$ g.cm⁻³. The phases were determined by the direct method and the parameters were refined anisotropically by full-matrix least squares to a final R=0.031 for 925 observed reflections. The bond lengths are normal with mean C-C and C-O values of 1.527 and 1.429 Å. Within experimental error, the molecule has *m* symmetry. The two axially oriented OH groups give rise to strain in the molecule which causes some flattening of the cyclohexane ring. The molecules are linked by a system of hydrogen bonds such that two OH groups are involved as donor and double acceptor, two as donor and acceptor and two as donor only. The O-(H)…O distances vary from 2.731 to 2.923 Å. There is some evidence of variation of C-O distances with hydrogen-bond environment; the greater distances corresponding to greatest involvement in the hydrogen bonding.

Introduction

Of the nine stereoisomers of inositol, 1,2,3,4,5,6-cyclohexanehexol, $C_6H_{12}O_6$, only myo-inositol, which is the biologically active isomer, has been studied previously by crystal structure determinations. These are of the anhydrous compound by Rabinowitz & Kraut (1964) and of the dihydrate by Lomer, Miller & Beevers (1963). Whereas myo-inositol, (I), has one axially oriented hydroxyl group, epi-inositol, (II), has two. This study was directed principally at an investigation of the effect on the molecular conformation of the axial hydroxyls attached to alternate carbon atoms around the cyclohexane ring. It complements a similar conformational study of the structure of the acyclic hexitols in the crystalline state (Jeffrey & Kim, 1970).

Needle-shaped transparent crystals elongated about **a** were obtained by slow evaporation from a solution of ethanol-water at room temperature. The crystals were multiple and frequently occurred in pairs which could be easily recognized both optically and by doubled reflections on X-ray films. Attempts to obtain single crystals from other solvents and at other than room temperatures were unsuccessful. The crystal and intensity data were measured on a FACS I automatic dif-

fractometer with Ni-filtered Cu $K\alpha$ radiation using a crystal pair of dimensions $0.45 \times 0.05 \times 0.11$ mm, such that the separate reflections could be resolved without corrections. The crystal density was measured by flotation in a mixture of n-hexane and bromoform at 19 °C. The crystal data are as follows:

Monoclinic, a=4.841 (3), b=14.727 (4), c=11.236 (4) Å, $\beta=115.85^{\circ}$; V=720.9 Å³, $D_m=1.662$, $D_x=1.660$ g.cm⁻³; Z=4, $\mu_{Cu}\kappa_{\alpha}=13.26$ cm⁻¹, ($\lambda_{Cu}\kappa_{\alpha}=1.5418$ Å).

Space group $P2_1/c$, from the absences of 0k0 with k odd, h0l with l odd. The intensities were measured with a

Fig. 1. ORTEP plot of epi-inositol, showing atomic notation and thermal ellipsoids. The molecule is viewed approximately normal to the central plane of the chair-shaped cyclohexane ring: C(1) and C(4) are below and above the plane, respectively.

Table 1. Fractional atomic coordinates and anisotropic thermal parameters in epi-inositol

The estimated standard deviations are given in parentheses and refer to the last decimal positions. The temperature factor expression used was exp $[-(h^2\beta_{11}+k^2\beta_{22}+l^2\beta_{33}+2hk\beta_{12}+2hl\beta_{13}+2kl\beta_{23})].$

 $\theta/2\theta$ scan at the rate of 2°/min with stationary background counts. The scan width was varied with 2θ from 2° at $2\theta = 10^\circ$ to 4° at the maximum value of $2\theta = 130^\circ$. Of the 1234 reflections recorded, 309 had

intensities above background of less than two standard deviations as estimated from counting statistics; these were recorded as unobserved. No absorption correc-

tions were included in the data reduction.

Structure determination and refinement

The 170 phases of the largest normalized structure amplitudes were generated using direct methods (Long, 1968) on an IBM Model 360/50 computer. The twelve distinctive peaks on the E map, calculated from one of the sixteen sets of phases, were consistent with a predicted model of the epi-inositol molecule. Structure factor calculations with a uniform isotropic temperature factor gave an initial R index of 0.36 for all reflections. The structure was refined isotropically and anisotropically to an index 0.06 using an IBM 1130 program for block-diagonal least-squares and the same weighting scheme as was used in the final refinement. (Shiono, 1968). All hydrogen atoms were located on a difference synthesis calculated with structure factors within sin $\theta = 0.65$ at the R index of 0.09. Final refinement with full-matrix least squares on the IBM 7090 computer (Shiono, 1966) included all parameters except the thermal parameters of the hydrogen atoms which were assumed to be the same as the carbon or oxygen atoms to which they are attached. The final parameters are given in Table 1 and the observed structure factors versus structure factors calculated from those parameters are listed in Table 2. The final R index was 0.031for observed and 0.049 for all measured reflections.

The weighting scheme, $w^{-1} = (a+b|F_o|+c|F_o|^2)$ with a=12.06, b=1.0, c=0.0083 was used for the final refinement. The thermal parameters are also illustrated by an *ORTEP* plot (Johnson, 1965) in Fig. 1, along with identification of the atoms. The bond lengths and bond angles are given in Table 3.

Discussion

axis. The dotted lines represent hydrogen bonds, with arrows denoting the donor direction. The molecule of epi-inositol, like that of myo-inositol, has the chair conformation with the minimum number

of axially oriented hydroxyl groups, in this case, two, O(2)H and O(6)H, see Fig. 1. The mirror symmetry perpendicular to the cyclohexane plane and passing through C(1) O(1) C(4) O(4), which is ideal for an isolated molecule, is closely maintained in the crystal structure. For the carbon and oxygen atoms, the devia-

Table 2. Observed and calculated structure factors for epi-inositol

The columns are: Index, $10|F_{obs}|$, $10|F_{calc}|$.* indicates unobserved reflections.

Table 3. Bond lengths and bond angles in epi-inositol

Estimated standard deviations in parentheses refer to the last decimal positions of respective values.

$$\frac{l(C-C) = 1.527 (2) \text{ Å}}{l(C-O) = 1.430 (7)} < (C-C-C) = 110.8 (2.1)^{\circ} < (C-C-C) = 110.5 (1.9)$$

The mean values and estimated standard deviations are calculated from

	<i>l=</i>	$\frac{\sum_{i=1}^{N} \left(\begin{array}{c} l_{i} \\ \sigma_{i}^{2} \end{array} \right) / \sum_{i=1}^{N} \left(\begin{array}{c} \frac{1}{\sigma_{i}} \end{array} \right)$	$\left(\frac{1}{2}\right), \sigma_{\text{mean}} = \left[$	$\frac{\sum_{i=1}^{N} (l-l_i)^2}{N-1}$] ^{1/2} .

tions from m symmetry are less than 0.01 Å. The methylene hydrogen atoms are also symmetrical within the rather large estimated errors in their positions. The hydroxyl hydrogen atoms depart significantly from this molecular symmetry. This is expected because the orientation of the OH groups is determined by the intermolecular hydrogen bonding rather than by intramolecular forces, and the m molecular symmetry is not included in the crystal structure symmetry (see Fig. 2).

The C-C bond lengths range from 1.523 to 1.530 Å with a mean of 1.527 Å. In myo-inositol, the range is 1.508 to 1.533 with a mean of 1.521 Å. These differences are not significant. The C-O bonds vary over a wider range of 1.419 to 1.439 Å. The two longer bonds, C(4)-O(4) 1.439 Å and C(1)-O(1) 1.435 Å are associated with oxygen atoms involved in three hydrogen bonds, whereas the four shorter distances 1.429 to 1.419 Å correspond to oxygen atoms involved in only one or two hydrogen bonds. This is a marginal observation in terms of the estimated errors and requires verification by means of a more precise investigation of a neutron diffraction study which could reveal any related correlation with O-H distances.

The intermolecular hydrogen-bonding is shown in Figs. 2 and 3. It consists of two branched infinite chains shown diagrammatically as follows:

$$\begin{array}{c} O(3) \rightarrow O(4) \rightarrow O(3) \rightarrow O(4) \\ \downarrow & \downarrow \\ O(6) & O(6) \end{array}$$

$$\begin{array}{c} O(1) \rightarrow O(5) \rightarrow O(1) \rightarrow O(5) \\ \downarrow \qquad \qquad \downarrow \\ O(2) \qquad \qquad O(2) \end{array}$$

The hydrogen bond distances and angles are given in Table 4. The intermolecular $O(H) \cdots O$ distances range from 2.731 to 2.923 Å and are comparable in magnitude to the intramolecular $O \cdots O$ distances. There is also one intermolecular $O \cdots O$ non-bonding distance less than 3.2 Å as given in Table 4.

The intramolecular $O(2) \cdots O(6)$ distance is 2.96 Å, as compared with 2.50 Å in an unstrained cyclohexane ring with 60° dihedral angles. The effect of this strain interaction as compared with the ideal model is illustrated in Fig. 4.

The Crystal Structure of 4,4'-Diacetoxy-5,5'-dimethyl-2,2'-bithiazolyl (C₁₂H₁₂N₂S₂O₄)*

BY K.J. PALMER, ROSALIND Y. WONG AND KAY S. LEE

(Received 18 December 1970)

The reaction product of α -mercapto acids with cyanogen undergoes unusual *N*-methylation in addition to esterification when treated with diazomethane and converts to the bicyclic symmetrical 4,4'-diketo- Δ^2 -bithiazolinyl. The structure of the bicyclic compound has been a moot question for many years. Some investigations favored two six-membered rings with a shared edge; others, two five-membered rings bonded together. A crystal-structure determination of 4,4'-diacetoxy-5,5'-dimethyl-2,2'-bithiazolyl proves that this compound consists of two five-membered rings joined by a C-C bond. The crystallographic data for the monoclinic crystals are $a = 13 \cdot 125 \pm 0.005$, $b = 4 \cdot 830 \pm 0.002$, $c = 10 \cdot 995 \pm 0.004$ Å, $\beta = 94 \cdot 09 \pm$ $0 \cdot 01^{\circ}$, Z = 2, space group P_{21}/c . The intensities of 1367 independent reflections were measured with an automatic diffractometer. Least-squares refinement with anisotropic thermal parameters for the ten heavy atoms and isotropic thermal parameters for the hydrogen atoms gave an *R* value of 0.050.

In their studies of the reaction of α -mercapto acids with cyanogen, Mutha & Ketchum (1968) found that the reaction between mercaptoacetic acid and cyanogen (Fig. 1) gave a white crystalline product which proved to be monocyclic. Cyclization can result in the formation of a five-membered ring [Fig. 1(*a*)] or a sixmembered ring [Fig. 1 (*b*)]. Their study of the ultraviolet (UV), infrared (IR), and nuclear magnetic resonance (n.m.r) spectra of this product and several derivatives did not furnish a clear distinction between the two structures.

To obtain additional information, Mutha & Ketchum synthesized a bicyclic compound whose structure after acetylation, was either that of Fig. 2(a) or 2(b). Their study of the UV, IR, and n.m.r. spectra and a dipole-moment determination again failed to provide an unequivocal assignment of structure. Attempts to grow crystals suitable for X-ray analysis, from the various derivatives of both the monocyclic and bicyclic

A C 27B – 9*

compounds, led to the selection of the diacetate derivative of the bicyclic compound for crystal-structure analysis. The compound turned out to be 4,4'diacetoxy-5,5'-dimethyl-2,2'-bithiazolyl, hereafter referred to as DDB.

Experimental

The material used in this investigation was provided by Professor R. Ketchum and Dr S. Mutha. Crystals suitable for X-ray analysis were grown from chloroform. The crystals are elongated prisms with **b** parallel to the long axis and (100) prominent. The crystals cleave easily, parallel to the **ab** plane, but cannot be cut perpendicular to **b** without introducing X-ray line broadening. Consequently, the intensity data were taken on an uncut specimen with dimensions of $0.07 \times$ 0.20×0.14 mm.

Multiple-level Weissenberg photographs showed that the only systematic absences are 0k0 when k is odd, and h0l when l is odd. These extinctions indicate space group $P2_1/c$ which was confirmed by the struc-
