(Received 31 July 1971)

#### Abstract

Three-dimensional intensity data have been collected both at room temperature and at $-160^{\circ} \mathrm{C}$ for the triiodides $\mathrm{CsI}_{3}$ and $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4} \mathrm{AsI}_{3}$. The present work confirms the conclusion of Tasman \& Boswijk [Acta Cryst. (1955), 8, 59] regarding the asymmetry and non-linearity of the $\mathrm{I}_{3}^{-}$ion in $\mathrm{CsI}_{3}$. The bond lengths in the symmetric $\mathrm{I}_{3}^{-}$ions in $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4} \mathrm{AsI}_{3}$ [2.919 (1) $\AA$ ] are somewhat longer than the values reported by Mooney-Slater [Acta Cryst. (1959), 12, 187], but are still shorter than the average I-I bond lengths observed for $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{3}(\mathrm{I})$ and $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{3}(\mathrm{II}), 2.935$ and $2.936 \AA$ respectively. The I-I bond lengths observed in different triiodides are compared, and the differences are discussed.

## Introduction

The configurations of $\mathrm{I}_{3}^{-}$ions in different crystals have aroused considerable interest (Brown \& Nunn, 1966; Migchelsen \& Vos, 1967; Wiebenga \& Kracht, 1969). The bond lengths and angles known with reasonable accuracy at the beginning of the present study are given in Table 1 $(a)$. The Table shows that for $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{7}$ the I-I bond length is significantly shorter than the average I-I bond lengths observed for the compounds $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{3}(\mathrm{I})$ and $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{3}(\mathrm{II})$. This does not hold for $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4} \mathrm{AsI}_{3}$ for which the bonds had been reported to be relatively short (Mooney-Slater, 1959; Rundle, 1961). The presence of the short distances in $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{7}$ at $-195^{\circ} \mathrm{C}$ cannot be attributed to the electrostatic crystal field as for all symmetric $\mathrm{I}_{3}^{-}$ions the calculated bond orders are independent of this field (Wiebenga \& Kracht, 1969). We have therefore tentatively assumed the presence of the short I-I bonds in $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{7}$ at $-195^{\circ} \mathrm{C}$ to be due to either a shrinkage of the weak I-I bonds at low temperature or to complex formation (the $\mathrm{I}_{3}^{-}$ions have strong interactions with neighbouring $\mathrm{I}_{2}$ molecules). To get more insight in this problem we have refined the crystal structures of $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4} \mathrm{AsI}_{3}$,
having symmetric $\mathrm{I}_{3}^{-}$ions, and of $\mathrm{CsI}_{3}$, having asymtric $I_{3}^{-}$ions, both at room and at low temperature.

## Discussion of the I-I bond lengths

## Influence of the temperature

The I-I bond lengths and angles observed in $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4} \mathrm{AsI}_{3}$ and in $\mathrm{CsI}_{3}$ at room temperature and at low temperature, are given in Table $1(b)$. We see that in both compounds the bond lengths at low temperature are equal to those at room temperature, so that it can be concluded that no shrinkage of the bonds occurs at low temperature.

## Symmetric $\mathrm{I}_{3}^{-}$ions

Comparison of the bond lengths in the different symmetric $\mathrm{I}_{3}^{-}$ions in Table 1 shows that there are significant differences between the lengths of the bonds. Values increasing from 2.904 to $2.943 \AA$ are observed when going from $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{7}$ via $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4} \mathrm{AsI}_{3}$ and $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{3}(\mathrm{I})$ (ion $A$ ) to $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{3}(\mathrm{I})$ (ion $B$ ). Consideration of the crystal structures shows that both for the $\mathrm{I}_{3}^{-}$ion $B$ in $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{3}(\mathrm{I})$, having the longest I-I distance, and for the $\mathrm{I}_{3}^{-}$ion in $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{7}$, having the
shortest I-I distance, there is a relatively strong interaction with neighbouring iodine atoms. The type of interaction is different, however, for the two ions. Ion $B$ is involved in intermolecular distances shorter than the van der Waals distance in such a way that a linear array I...I-I-I $\cdots$ I is formed [Fig. 1(a)], whereas for $\mathrm{I}_{3}^{-}$in $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{7}$ the short intermolecular $\mathrm{I} \cdots \mathrm{I}$ distances are roughly perpendicular to the $(\mathbf{I}-\mathrm{I}-\mathrm{I})^{-}$ion [Fig. $1(c)$ ]. For ion $A$ in $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{3}(\mathrm{I})$ the intermolecular interaction [Fig. $\mathrm{l}(b)$ ] is much smaller than for ion $B$, while for the $\mathrm{I}_{3}^{-}$ion in $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4} \mathrm{AsI}_{3}$ no short intermolecular distances are observed ('free' $\mathrm{I}_{3}^{-}$ion). This seems to suggest that the I-I bond in a free $\mathrm{I}_{3}^{-}$ion lies close to $2.920 \AA$. The presence of a linear array as shown in Fig. $1(a)$ appears to increase the I-I bond length, whereas the configuration of Fig. $1(c)$ causes a shortening of the bonds.
The lengthening of the bonds in ion $B$ has been estimated by doing a PPP calculation (Pariser \& Parr, 1953; Pople, 1953) for both the ions $A$ and $B$ in $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{3}(\mathrm{I})$. The $p$ orbitals used for each of the calculations are given in Fig. 2. The intra- and intermolecular distances were taken from the crystal structure, the electrostatic crystal field was not considered as this does not change the calculated lengths for the bonds in symmetric $I_{3}^{-}$ions (see introduction). The calculated bond orders $P$ are 0.690 for ion $B$ and 0.704 for ion $A$ ( $P=0.707$ for an isolated $\mathrm{I}_{3}^{-}$ion), so that the bonds for $B$ are expected to be longer than for $A$ in agreement with experiment. From the slope $\mathrm{d} R / \mathrm{d} P=$ -1.2 at $P=0.7$ of the $R(P)$ curve given by Wiebenga \& Kracht (1969; Fig. 2), $\Delta R$ is calculated at $0.017 \AA$, which is of the right order of magnitude.
The shortening of the bonds in the $\mathrm{I}_{3}^{-}$ion in $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{7}$ could not be made plausible from simple

PPP calculations, as in this case the complete threedimensional network consisting of $\mathrm{I}_{3}^{-}$ions and $\mathrm{I}_{2}$ molecules has to be considered. For this compound further theoretical work is required.

## Asymmetric $\mathrm{I}_{3}-$ ions

Theoretical calculations on free $\mathrm{I}_{3}^{-}$ions including the (electrostatic) crystal field, predict unequal bonds for $I_{3}^{-}$ions having asymmetric surroundings in the crystal. As long as the asymmetry is small, the average value of the bonds is expected to be negligibly larger than the lengths observed for free symmetric $\mathrm{I}_{3}^{-}$ions. For highly asymmetric ions a small increase of the average bond length is expected [see $R(P)$ curve in Wiebenga \& Kracht, 1969]. Table 1 shows that for the asymmetric ions in $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{3}(\mathrm{II})$ and in $\mathrm{CsI}_{3} \frac{1}{2}\left[R_{12}+\right.$ $\left.R_{23}\right]$ is, within experimental error, equal to the length of the I-I bond of ion $B$ in $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{3}(\mathrm{I})$ and larger than the value observed for the free $\mathrm{I}_{3}^{-}$ion in $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4} \mathrm{AsI}_{3}$.

Fig. 1. Shortest intermolecular distances in the neighbourhood of (a) ion $B$ in $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{3}(\mathrm{I}),(b)$ ion $A$ in $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{3}(\mathrm{I})$ and (c) the $\mathrm{I}_{3}{ }^{-}$ion in $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{7}$.

| $\mathrm{CSI}_{3}$ | $m$ | 177.9 (1) | 2.840 (4) | 3.042 (4) | $2 \cdot 941$ (2) | 4.01 | Present study. |
| $\mathrm{CsI}_{3}\left(-160^{\circ} \mathrm{C}\right)$ | $m$ | 178.00 (6) | $2 \cdot 842$ (2) | 3.038 (2) | 2.940 (1) | 3.97 | Present study. |
| $\mathrm{NH}_{4} \mathrm{I}_{3}$ | $m$ | $180 \cdot 0$ (1) | 2.791 (4) | $3 \cdot 113$ (4) | $2 \cdot 952$ (2) | $3 \cdot 88$ | Cheesman \& Finney, 1970. |

Consideration of the crystal structures shows that this lengthening can be ascribed to intermolecular interaction.

For the asymmetric ions in $\mathrm{NH}_{4} \mathrm{I}_{3}$ the value for $\frac{1}{2}\left[R_{12}+R_{23}\right]$ is slightly larger than the values observed for the remaining asymmetric $I_{3}^{-}$ions. A small elongation relative to these ions can be expected as: (1) the intermolecular distances in $\mathrm{NH}_{4} \mathrm{I}_{3}$ are somewhat shorter than, for instance, in the isomorphous compound $\mathrm{CsI}_{3}$, and (2) the asymmetry of the ions is relatively high. It must further be mentioned that accurate work on $\mathrm{NH}_{4} \mathrm{I}_{3}$ is hampered by its rapid decomposition, so that it cannot be excluded that the standard deviations reported by Cheesman \& Finney (1970) are lower estimates of the errors in the structure.

## Structure refinements

Crystals of $\mathrm{CsI}_{3}$ were obtained by adding iodine to an equivalent amount of CsI dissolved in ethanol and slow evaporation of the solute. Crystals of $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4} \mathrm{AsI}_{3}$ were grown by diffusion from solutions of $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}$ AsI and $\mathrm{I}_{2}$ in ethanol, the solutions being put in the vertical parts of a U-shaped tube having pure ethanol between glass filters in its horizontal part. Large crystals measuring approximately $0.2 \times 0.3 \times 0.4 \mathrm{~mm}$ were obtained after some days. Details of the experimental work are given in Table 2. For the low temperature work the crystals were cooled down to $-160^{\circ} \mathrm{C}$ by a stream of cold nitrogen gas (for apparatus used, see van Bolhuis, 1971).

## Details of the structures

The bond lengths and angles in $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4} \mathrm{AsI}_{3}$ and $\mathrm{CsI}_{3}$ at $-160^{\circ} \mathrm{C}$ are listed in Table 7.

The [010] projection of the structure of $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4} \mathrm{AsI}_{3}$ is given in Fig. 3, both the $\mathrm{I}_{3}^{-}$ion and the $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4} \mathrm{As}^{+}$ group lie at special positions with symmetry 2. It is seen that the $\mathrm{I}_{3}^{-}$ions have no short intermolecular distances to neighbouring atoms. The As atom is approximately tetrahedrally surrounded by benzene rings, which are planar within experimental error. The suggestion given in the literature (Brown \& Nunn,

Fig. 2. The $p$-orbitals used in the bond order calculations for the $\mathrm{I}_{3}^{-}$ions in $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{NI}_{3}(\mathrm{I})$. The orbitals of the 'central' ion ( $A$ or $B$ ) are dotted. The structure is idealized in such a way [compare with Fig. 1(a) in Migchelsen \& Vos, 1967], that only angles of $90^{\circ}$ and $180^{\circ}$ are considered. Only part of a two-dimensional layer is taken into account.

Table 7. Distances and angles in $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4} \mathrm{AsI}_{3}$ (a) and in $\mathrm{CsI}_{3}(b)$ at $-160^{\circ} \mathrm{C}$
The standard deviations in the Table are obtained from those given in Tables 4 and 6 after multiplication by $1 \cdot 5$, as the standard deviations from the least-squares program are lower estimates of the errors in the structure (Visser \& Vos, 1971).
(a)

1966; Bernstein \& Herbstein, 1968), that the twofold symmetry of the $\mathrm{I}_{3}^{-}$ion is not genuine but due to

Fig. 3. The structure of $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4} \mathrm{AsI}_{3}$ seen along the [010] axis. As and $I(1)$ lie on the twofold axes $\left[\frac{1}{4}, y, \frac{1}{4}\right]$ and $\left[\frac{1}{4}, y, \frac{3}{4}\right]$ respectively.

Fig.4. The structure of $\mathrm{CsI}_{3}$ seen along the [010] axis.
disorder, is not supported by the thermal parameters of the present low temperature study.
In $\mathrm{CsI}_{3}$ all atoms lie in the mirror plane $x=0.25$, and in symmetrically related planes. Fig. 4 clearly shows that the surroundings of the $\mathrm{I}_{3}^{-}$ion are strongly asymmetric, and that there are approximately linear arrays of type I-I-I $\cdots$ I.

We wish to thank Professor Aafje Vos for many valuable discussions and Dr D. Kracht for doing the PPP calculations. The calculations were done at the Groningen University Computing Centre.
