A Neutron Diffraction Study of the Structure of L-Glutamic Acid. HCl

BY A. SEQUEIRA, H. RAJAGOPAL AND R. CHIDAMBARAM

Nuclear Physics Division, Bhabha Atomic Research Centre, Trombay, Bombay-85, India

(Received 6 December 1971)

A neutron diffraction study of L-glutamic acid hydrochloride, $C_5H_{16}O_4N$. Cl, has been carried out. The structure is orthorhombic, space group $P2_12_12_1$, with four molecules per unit cell. The cell parameters are: $a=5\cdot151$ (6), $b=11\cdot79$ (2) and $c=13\cdot35$ (2) Å. Intensities of 639 (606 non-zero) independent reflexions have been measured at a wavelength of 1.406 Å, using the diffractometer in symmetrical setting. The positions of the ten hydrogen atoms in the asymmetric unit have been determined from a Fourier map of the nuclear scattering density computed using the phases from the X-ray heavy-atom positions. The structure has been refined to a final conventional R value of $4\cdot3\%$ by the method of least-squares. It consists of molecules hydrogen-bonded in zigzag chains along the c direction. Details of hydrogen bonding and molecular conformation are discussed. The average C-H bond length is $1\cdot090$ (11) Å. The average values of the C-C-H and H-C-H angles are $109\cdot4$ (7) and $106\cdot0$ (12)°, while those of the C-N⁺-H and H-N⁺-H angles are $109\cdot9$ (7) and $109\cdot0$ (9)°.

Introduction

A detailed knowledge of the hydrogen atom positions and the side group conformations in amino acids is of considerable interest in the calculation of the configuration of the side groups associated with polypeptide chains. This paper reports a precision neutron diffraction study of the structure of L-glutamic acid. HCl as part of the program of studies currently in progress in our laboratory on the structure and hydrogen-bonding properties of amino-acids. A two-dimensional Xray study of this structure was carried out by Dawson (1953) but the hydrogen atom positions were not determined.

Experimental

Large, clear and well formed crystals of L-glutamic acid.HCl, $C_5H_9O_4N$.HCl, were easily obtained by slow evaporation from a saturated aqueous solution with excess 20% hydrochloric acid. The crystals were

generally of tabular shape and deliquesced slightly on exposure to air. The principal faces were $\{001\}$ and the bounding faces were of the forms $\{011\}$ and $\{101\}$. The density of the crystals, measured by flotation in a mixture of carbon tetrachloride and ethylacetate, was 1.524 g.cm⁻³.

Neutron intensity data were recorded using the 4circle diffractometer, 3D-FAD (Momin, Sequeira & Chidambaram, 1969), at the CIRUS reactor in Trombay. The specimen crystal used was in the shape of a five-sided prism (volume=27 mm³) with height=5.1mm along the a direction and with four of its side faces being (001), $(00\overline{1})$, $(0\overline{1}1)$ and $(0\overline{1}1)$ and the fifth one cut roughly parallel to (010). The widths of these faces were 2.5, 2.3, 0.9, 1.4 and 1.9 mm respectively. The crystal was given a thin coating of an adhesive (brand name: Stickfast) to prevent exposure to air, and mounted on the diffractometer with its a axis parallel to the φ axis. The cell parameters and crystal orientation were refined on the basis of the optimized 2θ , χ and φ values for some 25 strong reflexions, using the program REFINE (Srikanta & Sequeira, 1968). The refined values of the cell constants are listed in Table 1 along with other crystal data. The systematic absences were consistent with the space group $P2_12_12_1$.

The integrated intensities of 639 independent reflexions within the limit $\sin \theta/\lambda = 0.57$ [$\lambda = 1.406$ (1) Å] were recorded in the 'bisecting position' using the θ -2 θ coupled step-scanning technique. Two standard reflex-

ions were recorded after every 20 reflexions to keep a check on the stability of the crystal and that of the counting equipment. The reproducibility of the standard intensities was within 4%, and there was no deterioration of the crystal quality. The second order contamination in the beam was avoided by using germanium (331) as the monochromator. The effects of multiple reflexions were checked for the h00 reflexions by examining their peak intensities as function of the rotation about the scattering vectors and found to be negligible.

The integrated intensities were reduced to F_o^2 by applying the standard Lorentz and absorption corrections using our program *DATARED* (Srikanta, 1968) which includes the absorption correction program *ORABS* (Wehe, Busing & Levy, 1962) as a subroutine. An absorption coefficient of 2.75 cm⁻¹ (measured) was used. The transmission factors ranged from 0.448 to 0.608.

Fig. 1. Variation of observed and estimated extinction factors as a function of the parameter X.

Refinement

The positions of the ten hydrogen atoms in the asymmetric unit were obtained from a three-dimensional Fourier synthesis of the nuclear scattering density computed using the program FORDAP (Zalkin, 1962) with the observed F_o 's and phases as calculated from Dawson's (1953) heavy-atom positions. All the structural parameters were then subjected to a series of full-matrix least-squares refinements (on F^2), first with isotropic and then with anisotropic temperature factors, using the program XFLS (Busing, Martin &

Levy, 1962). In the anisotropic refinement the parameters of the heavy atoms and the hydrogen atoms were refined in alternate cycles as it was not possible to refine all the parameters in the same cycle. The function minimized was $\sum \omega (F_o^2 - |F_c|^2)^2$ with initial weights $\omega = [\sigma_s^2(F_o^2) + (0.1F_o^2)^2]^{-1}$ where $\sigma_s(F_o^2)$ are the standard errors based on counting statistics. Reflexions for which $|F_c|^2/\sin 2\theta > 100$ were not used initially.

Extinction

Severe extinction effects became apparent during the refinement, resulting in unreasonable values for some

Table 2. Final positional and thermal parameters

All the values are multiplied by 10⁴ and their standard deviations (in units of the last digit) are given in parentheses. The form of the anisotropic temperature factor is

	$\exp\left[-(\beta_{11}h^2+\beta_{22}k^2+\beta_{33}l^2+2\beta_{12}hk+2\beta_{13}hl+2\beta_{23}kl)\right].$

of the thermal parameters even though many strong reflexions were omitted. Hence, a correction for secondary extinction was applied in the following way (Zachariasen, 1967):

$$F_o^2 \text{ (corrected)} = F_o^2 / Y$$

$$Y = [1 + 2X]^{-1/2}$$

$$X = G Q_o \overline{T}$$

where $Q_o[=(\lambda^3/v^2) |F_c|^2/\sin 2\theta]$ is the reflectivity, \overline{T} $-(1/A)\frac{dA}{d\mu}$ is the mean absorption weighted path length and $G = \gamma/\lambda \{1 + (\gamma/\lambda g)^2\}^{-1/2}$ is an isotropic extinction parameter. \overline{T} for each reflexion was computed by a modification of the program ORABS (Wehe, Busing & Levy, 1962) and transferred to the least-squares program. The extinction parameter Gwas refined along with other parameters (see, for example, Coppens & Hamilton, 1970) by suitable modifications of the program XFLS. Details of the extinction treatment will be given separately (Sequeira, Rajagopal & Chidambaram, 1972). The final value of G was $1.44 (10) \times 10^5$, which corresponds to an equivalent mosaic spread of 0.4 sec of arc. Some 40 reflexions for which the extinction factor Y was less than 0.25 were omitted from the refinement as they were significantly undercorrected (see Fig. 1).

An error analysis based on F_o^2 values corrected for extinction indicated the suitability of the weighting scheme $\omega = 1/\sigma^2 = [0.35 + 0.04545|F_c|^2/\sin 2\theta]^{-2}$. This scheme used in the final stages of refinement resulted in the following values for the discrepancy factors:

No. obs.	R_1	R_2	R_{ω}
636	0.0559	0.1096	-
566	0.0432	0.0683	0.0898
$(F_a^2 > \sigma; Y > 0.25)$			

where $R_1 = \sum ||F_o| - |F_c|| / \sum |F_o|$; $R_2 = \sum |F_o^2 - |F_c|^2 | / \sum F_o^2$ and $R_\omega = [\sum \omega |F_o^2 - |F_c^2||^2 / \sum \omega F_o^3]^{1/2}$. The values of the scattering amplitudes (in units of 10^{-12} cm) used were: H = -0.372, C = 0.6626, N = 0.94, O = 0.575 and Cl =0.96 (Shull, 1971). The final positional and thermal parameters are listed in Table 2, and the observed and calculated structure factors are compared in Table 3.

Discussion of the structure

The X-ray structure of L-glutamic acid. HCl given by Dawson (1953) is basically correct. However, there are significant differences between Dawson's heavy atom parameters and those obtained in this study. For example, the systematic long-short-long type of variation in bond lengths along the carbon chain pointed out by Dawson is not observable. The distances and angles within the molecule, computed using the program ORFFE (Busing, Martin & Levy, 1964), are given in Table 4. The distances and angles involving the nonhydrogen atoms are compared in Table 5 with the weighted average values for un-ionized amino acids reported by Sundaralingam & Putkey (1970). The two seem to agree fairly well. The bond distances except C(4)-C(5) in the side chain are close to their normal values. The value of C(4)-C(5) (1.476 Å), however, is somewhat shorter than the value of 1.50 Å normally associated with $C_{sp2}-C_{sp3}$ single bonds.

Table 4. Bond distances (Å) and angles (°) within the molecule

The standard deviations are given in parentheses.

* Sundaralingam & Putkey (1970).

The average distances and angles involving the hydrogen atoms are in good agreement with the values observed in other amino acid crystals. For example, the average C-H distance of 1.090 (11) Å obtained here is close to 1.096 Å observed in L-alanine (Lehmann, Koetzle & Hamilton, 1972); the average values of 109.4 (7)° for the C-C-H angle, 106.0 (12)° for the H-C-H angle, 109.9 (7)° for the C-N⁺-H angle and 109.0 (9)° for the H–N⁺–H angle also compare fairly well with the corresponding values of 110.2, 108.7, 109.8 and 109.1° observed in L-alanine.

Molecular conformation

A stereoscopic picture of the molecule drawn using the program ORTEP (Johnson, 1965) is shown in Fig. 2 and its conformation in Fig. 3. The torsion angles about various bonds are also given in Fig. 3 following the nomenclature recommended by the IUPAC-IUB Commission (1970).

The α -carbon atom [C(2)] is planar with the carboxyl group C(1) O(1) O(2), and the least-squares plane through these is

 $3 \cdot 197X - 3 \cdot 233Y + 9 \cdot 804Z - 9 \cdot 000 = 0$,

the maximum deviation from the plane being 0.01 Å for C(1). The ammonium nitrogen is displaced from this plane by 0.47 Å, such that the value of the torsion angle ψ (1), {N-C(2)-C(1)-O(2)}, is negative as is usually observed (Lakshminarayanan, Sasisekharan & Ramachandran, 1967) in L-amino acids. The α -NH₃⁺ group is staggered relative to the substituents on C(2) as shown in Fig. 3(b).

The side chain conformation is normal, with C(4) taking the most favourable staggered position *trans* to C(1) [Figure 3(c)] and C(5) being *trans* to C(2) across C(3)-C(4) [Fig. 3(d)]. The end carboxyl group C(5) O(3) O(4) is planar with C(4), and the corresponding least-squares plane is

3.760X + 7.964Y + 1.390Z - 5.899 = 0.

Fig. 2. A stereoscopic drawing of the molecule.

Fig. 3. Torsional conformations looking down bonds: (a) C(2)-C(1); (b) C(2)-N; (c) C(2)-C(3); (d) C(3)-C(4); (e) C(4)-C(5); (f) C(5)-O(4); (g) C(1)-O(1).

Table 6. Hydrogen bonds in L-glutamic acid. HCL

Fig. 4. A stereoscopic drawing of the unit cell viewed along the a axis.

This plane is tilted by 13.9° from the plane defined by the previous adjacent three atoms C(5) C(4) C(3) while the corresponding tilt in L-aspartic acid is about 50° (Derissen, Endeman & Peerdeman, 1968).

The dihedral angles 89.6 (4), 89.9 (5) and 88.5 (5)° between the H–C–H and C–C–C planes through the tetrahedral carbon atoms C(2), C(3) and C(4) respectively are close to the expected value of 90°.

Hydrogen bonding

The structure is strongly hydrogen-bonded. Each molecule is involved in five hydrogen bonds, two from the carboxyl hydrogens H(1) and H(2) and three from the amino hydrogens H(3), H(4) and H(5). The distances and angles characterizing these hydrogens bonds are listed in Table 6. Adjacent molecules are linked into zigzag chains along the direction of the *c* axis by means of strong hydrogen bonds of the type O(1)-H(1)···O(3) between the carboxyl groups. These chains are then held together by the N-H···O bonds, while the N-H···Cl and the O-H···Cl bonds provide additional links between them. A stereoscopic drawing of the unit cell is shown in Fig. 4.

Technical assistance given by Shri S. N. Momin during the data collection is gratefully acknowledged.
