(Received 11 December 1972; accepted 24 January 1973)

#### Abstract

The crystal structure of bis-(6-aminohexanoato)copper(II) dihydrate has been determined from 993 independent, visually estimated reflexions, which were recorded using equi-inclination Weissenberg photographs and $\mathrm{Cu} K \alpha$ radiation. The monoclinic, $P 2_{1} / n$ unit cell has the dimensions $a=8.550$ (2), $b=20.068(3), c=5 \cdot 145(1) \AA$, and $\beta=105 \cdot 85(2)^{\circ}$; it contains four asymmetric units. The structure was solved by using standard Fourier techniques, and refined by the method of least squares $(R=0.066)$. Four aminohexanoate molecules are coordinated to a central copper atom, two of them via a carboxylate oxygen atom and the other two via a nitrogen atom $[\mathrm{Cu}-\mathrm{O}=1.967$ (5) $\AA, \mathrm{Cu}-\mathrm{N}=1.994$ (6) $\AA]$. These centrosymmetric ligand atoms form an almost square plane, and they are trans with respect to each other. The second oxygen atoms of the two carboxylate groups bound, one above and one below the 'square' plane, complete a distorted octahedron [ $\mathrm{Cu}-\mathrm{O}=2.768$ (6) $\AA$ ]. Each ligand molecule binds two copper atoms, forming a two-dimensional network; the networks are connected by hydrogen bonds formed between the amino nitrogen atoms and carboxylate oxygen atoms, and via water molecules which are hydrogen bonded to nitrogen and carboxylate oxygen atoms.

## Introduction

As part of a general study on copper-protein interaction, the copper ion complexes of 6 -aminohexanoic acid are being investigated. This particular ligand is intended as a model for carboxylate and $\varepsilon$-amino side chains present in proteins. In a solution study, we have previously shown that the carboxylate group rather than the $\varepsilon$-amino group of aminohexanoic acid interacts with copper(II) ions (Ö̈sterberg \& Toftgård, 1972). In the corresponding copper(I) system, on the other
hand, our data indicate that copper(l) is bound to the $\varepsilon$-amino group (Österberg \& Sjöberg, 1972). Here, we report the crystal structure of bis-(6-aminohexanoato)copper(II) dihydrate, which clearly demonstrates that copper(II) ions interact with the $\varepsilon$-amino group in the solid state.

## Experimental

The crystals used in this study were prepared by one of the methods developed by Sjöberg (doctoral dissertation, to be published): bis-(1,5-cyclooctadiene)-
copper(I) perchlorate, synthesized as described by Manahan (1966), was dissolved in a neutral water solution of 6 -aminohexanoic acid; the cyclooctadiene was removed by extraction with ether; when oxygen from the air was gradually introduced, oxidation occurred and violet crystals of bis-(6-aminohexanoato)copper(II) dihydrate separated. The results of chemical analyses are:

Found: $\mathrm{Cu}=17 \cdot 9, \mathrm{C}=40 \cdot 1, \mathrm{~N}=7 \cdot 8, \quad \mathrm{H}_{2} \mathrm{O}=10 \cdot 0 \%$
Calc.: $\quad \mathrm{Cu}=17 \cdot 7, \mathrm{C}=40 \cdot 0, \mathrm{~N}=7.8, \mathrm{H}_{2} \mathrm{O}=10 \cdot 0 \%$. $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{2} \mathrm{~N} \cdot \frac{1}{2} \mathrm{Cu} . \mathrm{H}_{2} \mathrm{O}$. F.W. 179.96. Monoclinic, $a=$

$8.550 \pm 0.002, \quad b=20.068 \pm 0.003, \quad c=5.145 \pm 0.001 \AA$, $\beta=106 \cdot 85 \pm 0.02^{\circ}, D_{m}=1 \cdot 40, D_{c}=1.41 \mathrm{~g} \mathrm{~cm}^{-3}, U=$ $844 \cdot 9 \AA^{3}, \quad Z=4, \quad F(000)=382, \lambda\left(\mathrm{Cu} K \alpha_{1}\right)=1 \cdot 5405 \AA$, $\lambda\left(\mathrm{Cu} \mathrm{K} \mathrm{\alpha}_{2}\right)=1.5443 \AA$.

The space group, $P 2_{1} / n$, was determined from systematic extinctions: $0 k 0$, absent for odd $k ; h 0 l$, absent for odd $h+l$. (The setting differs from those given in International Tables for X-ray Crystallography, 1952.)

The density was measured by the flotation method, using a mixture of carbon tetrachloride and 1,2 -dimethylbenzene. The unit-cell dimension was obtained from a powder photograph taken with a Guinier camera at $21^{\circ}$, using $\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}$ as an internal standard. The parameters, $\lambda\left(\mathrm{CuK} \alpha_{1}\right)=1.54051 \AA$ and $a\left[\mathrm{~Pb}\left(\mathrm{NO}_{3}\right)_{2}\right]=7 \cdot 8566 \AA$, were those listed in International Tables for X-ray Crystallography (1962). The cell parameters are based on a least-squares refinement using $41 d$ values and a modified version of the computer program LETAGROP (Ingri \& Sillén, 1965); the observed and calculated $d$ values, and the corresponding intensities are listed in Table 1.

Equi-inclination, multiple-film Weissenberg data were recorded by rotating the crystal about the $a$ axis ( $0 k l$ ) and the $c$ axis $(h k 0-h k 4)$. A crystal with the dimensions $0.3 \times 0.3 \times 0.4 \mathrm{~mm}$ was used. The intensities were visually estimated. They were corrected for the Lorentz and polarization factors, and placed upon a common scale by correlation among equivalent reflexions recorded on the two axes; a total of 993 independent reflexions were recorded.

## Structure determination and refinement

For the space group $P 2_{1} / n$ there are four equivalent positions: $\pm\left(x, y, z ; \frac{1}{2}+x, \frac{1}{2}-y, \frac{1}{2}+z\right)$, and, since there are only two copper atoms in the unit cell they were assigned the positions $0,0,0$ and $\frac{1}{2}, \frac{1}{2}, \frac{1}{2}$. A three-dimensional Fourier synthesis, using phases calculated from the copper atom, revealed the remaining non-hydrogen atoms, except the oxygen atoms of the water molecules. Those positions of the atoms first found were refined using block-diagonal least-squares calculations and isotropic temperature factors. Then a difference

Fourier synthesis was calculated and the water oxygen atoms were located. Structure factors calculated at this stage had a reliability index, $R$, of $0.22 ; R=\Sigma| | F_{o} \mid-$ $\left|F_{\mathrm{c}}\right||/ \Sigma| F_{o} \mid$. Three cycles of full-matrix least-squares refinement reduced $R$ to 0.132 . Anisotropic temperature factors and individual scale factors for the five layers further reduced $R$ to 0.084 . Through another difference Fourier synthesis the hydrogen atoms were located. Their peak electron densities ranged from 0.8 to $1 \cdot 2 \mathrm{e} \AA^{-3}$, except for the hydrogen atom $\mathrm{H}(13)$ which had a peak density of $0.5 \mathrm{e}^{-3}$. When the refinement was continued, now including the hydrogen atoms with isotropic temperature factors, $R$ dropped to 0.072 .

During the final refinement, the calculated structure factors were corrected for the anomalous dispersion of copper, $\Delta f^{\prime}=-2.15$ and $\Delta f^{\prime \prime}=0.75$ (Cromer, 1965). The least-squares refinement was terminated when the shifts of the parameters were less than 0.02 of the cal-
culated standard deviations. The final $R$ is 0.066 . An additional difference Fourier synthesis was calculated; thepeaks, positive and negative, were all below $0.5 \mathrm{e} \AA^{-3}$.

The final parameters of the atoms are listed in Tables 2 and 3. The table of observed and calculated structure factors is available.*

The scattering factors used for $\mathrm{C}, \mathrm{N}, \mathrm{O}$, and $\mathrm{Cu}^{+}$ were those described by Doyle \& Turner (1968), and those for the hydrogen atoms were obtained from Stewart, Davidson \& Simpson (1965). In the final cycles of refinement, weights were used according to the formula described by Cruickshank (1965):

$$
w=\left(45 \cdot 0+F_{o}+0.015 F_{o}^{2}+0.0002 F_{o}^{3}\right)^{-1}
$$

* The table has been deposited with the National Lending Library, England, as Supplementary Publication No. 30071. Copies may be obtained through the Executive Secretary, International Union of Crystallography, 13 White Friars, Chester CH 11 NZ, England.

block-diagonal refinement, originally written by $O$. Lindgren, University of Göteborg; $D R F$, Fourier summations, and $\operatorname{DISTAN}$, angles and distances and their standard deviations, originally written by A . Zalkin, University of California, Berkeley. The drawings were produced by $O R T E P$, written by Johnson (1965).

## Description of the structure

The atomic arrangement in the unit cell of bis-(6aminohexanoato)copper(II) dihydrate is shown in Fig. 1. The interatomic distances and angles, as well as their standard deviations, are given in Table 4.

Four aminohexanoate molecules are coordinated to each copper atom, two of them via a carboxylate oxygen atom and the other two via a nitrogen atom. In the cell, each copper atom is centrosymmetrically surrounded by these four ligands (Fig. 1). Each ligand coordinates two copper atoms forming two-dimensional, four-connected networks. These are parallel to the (101) plane.

The coordination about the copper atom is planar for the four closest, centrosymmetrical ligands which nearly form a square (Fig. 2). These two oxygen and nitrogen atoms are trans with respect to each other. The distances $\mathrm{Cu}-\mathrm{O}(1)=1.967$ (5) and $\mathrm{Cu}-\mathrm{N}=$ 1.994 (6) $\AA$ are in close agreement with those determined previously for similar copper(II) structures (Freeman, 1967; Cingi, Guastini, Musatti \& Nardelli, 1970). The second oxygen atoms, $O(2)$ and $O\left(2^{\prime \prime}\right)$, of the two carboxylate groups bound, one above and one below the 'square' plane, complete a distorted octahedron at 2.768 (5) $\AA$ from the copper; thus, the coordination number of the copper atom is six. The distortion is clearly indicated by the fact that the angles of $\mathrm{O}(1)-\mathrm{Cu}^{\prime}-\mathrm{O}(2)$ and $\mathrm{O}\left(1^{\prime \prime}\right)-\mathrm{Cu}^{\prime}-\mathrm{O}\left(2^{\prime \prime}\right)$ are equal to $51.8(2)^{\circ}$, and thus both of these $\mathrm{Cu}-\mathrm{O}$ bonds are bent in the direction of their neighbouring oxygen atoms, $\mathrm{O}(1)$, (Fig. 2).

Table 5. Least-squares planes
(a) Coefficients

The equations of the planes are expressed in the form

$$
A X+B Y+C Z=D
$$

where $X, Y$, and $Z$ are Cartesian coordinates obtained from the fractional coordinates $x, y$, and $z$ by the transformation:

| $X=8.5500 x-1.4914 z$ |  |  |  |  |  |
| :---: | :--- | :---: | :---: | :---: | :---: |
|  |  | $Y=20.068 y$, | and | $Z=4.9241 z$. |  |
| Plane |  | $A$ | $B$ | $C$ | $D$ |
| 1 | $\mathrm{O}(1) \mathrm{O}(2) \mathrm{C}(6) \mathrm{C}(5)$ | 0.39518 | 0.79050 | -0.46791 | 8.2042 |
| 2 | $\mathrm{NC}(1) \mathrm{C}(2) \mathrm{C}(3) \mathrm{C}(4) \mathrm{C}(5) \mathrm{C}(6)$ | -0.68147 | -0.04565 | -0.73043 | -6.0654 |

(b) Deviations from planes $(\AA)$
(The figures within the parentheses were not included in the calculation of the plane.)

|  |  |  |  |  | $\Delta$ (1) |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | $\begin{gathered} \mathrm{O}(1) \\ -0.004 \end{gathered}$ | $\begin{gathered} \mathrm{O}(2) \\ -0.005 \end{gathered}$ | $\begin{gathered} C(5) \\ +0.012 \end{gathered}$ | $\begin{gathered} C(6) \\ -0.003 \end{gathered}$ | $\begin{gathered} \mathrm{Cu}^{\prime} \\ (-0.03 \end{gathered}$ |  |  |  |
|  |  |  |  |  | $\Delta$ (2) |  |  |  |  |  |
| N -0.012 | C(1) +0.113 | $\mathrm{C}(2)$ | $\mathrm{C}(3)$ | $\begin{gathered} C(4) \\ -0.099 \end{gathered}$ | $\begin{gathered} C(5) \\ -0.062 \end{gathered}$ | $\begin{gathered} \mathrm{C}(6) \\ +0 \cdot 128 \end{gathered}$ | $\begin{gathered} \mathrm{Cu}^{\prime} \\ (+1 \cdot 404) \end{gathered}$ | $\begin{gathered} \mathrm{Cu}^{\mathrm{v}} \\ (+0 \cdot 239) \end{gathered}$ | $\begin{gathered} \mathrm{O}(1) \\ (+1 \cdot 329) \end{gathered}$ | $\begin{gathered} \mathrm{O}(2) \\ (-0.833) \end{gathered}$ |
| $-0.012$ | $+0 \cdot 113$ | $-0.035$ | $-0.033$ | $-0.099$ | $-0.062$ | $+0 \cdot 128$ | $(+1 \cdot 404)$ | $(+0 \cdot 239)$ | $(+1 \cdot 329)$ | $(-0.833)$ |

The following three planes formed by the centrosymmetric ligand atoms all pass through the central copper atom by symmetry (Fig. 2): $\mathrm{O}(1) \mathrm{N}^{\prime \prime \prime} \mathrm{O}\left(1^{\prime \prime}\right) \mathrm{N}^{\mathrm{iv}}$, (plane $A$ ); $\mathrm{O}(1) \mathrm{O}(2) \mathrm{O}\left(1^{\prime \prime}\right) \mathrm{O}\left(2^{\prime \prime}\right)$, (plane $B$ ); $\mathrm{O}(2) \mathrm{N}^{\prime \prime \prime} \mathrm{O}\left(2^{\prime \prime}\right) \mathrm{N}^{\mathrm{iv}}$, (plane $C$ ). The angle between the 'square' plane (plane $A$ ) and plane $B$ is $91 \cdot 2^{\circ}$, that between plane $B$ and plane $C$ is $93 \cdot 3^{\circ}$, and that between plane $B$ and the plane of the carboxylate group (plane 1 of Table 5) is equal to $0.7^{\circ}$.
Bond lengths and angles for the ligand molecule are listed in Table 4. The $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{N}$ bond lengths, and the corresponding angles, agree with the average values obtained from previously determined structures. The difference between the $\mathrm{C}(6)-\mathrm{O}(1)$ and the $\mathrm{C}(6)-\mathrm{O}(2)$ bond lengths reflects the difference in the strength of the coordinate bonds in which the oxygen atoms, $\mathrm{O}(1)$ and $\mathrm{O}(2)$, are involved. The carboxylate group, $\mathrm{O}(1) \mathrm{O}(2) \mathrm{C}(6) \mathrm{C}(5)$, is planar; its least-squares plane forms an $87.9^{\circ}$ angle with the plane defined by the chain $\mathrm{NC}(1) \mathrm{C}(2) \mathrm{C}(3) \mathrm{C}(4) \mathrm{C}(5) \mathrm{C}(6)$ (plane 1 and plane 2 in Table 5).

The two-dimensional networks are linked together by hydrogen bonds (Fig. 3). The water molecule, $\mathrm{H}(1) \mathrm{O}(3) \mathrm{H}(2)$, has contacts with three different coordination spheres via the carboxylate oxygen atoms, $\mathrm{O}\left(2^{\mathrm{vi}}\right)$ and $\mathrm{O}\left(2^{\mathrm{vii}}\right)$, and the hydrogen atom $\mathrm{H}(4)$ of the amino group. The remaining hydrogen, $\mathrm{H}(3)$, of the amino group, is bonded to the carboxylate oxygen atom $\mathrm{O}\left(1^{\prime}\right)$, (Fig. 3). The hydrogen bond parameters are listed in Table 6.

Table 6. Hydrogen bond parameters

| Donor $(X)$ | Acceptor $(Y)$ | Hydrogen | $X-\mathrm{H} \cdots$ | $X-\mathrm{H}$ | $X \cdots Y$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{O}(3)$ | $\mathrm{O}\left(2^{\text {vi }}\right)$ | $\mathrm{H}(1)$ | $156^{\circ}$ | $0.68 \AA$ | $2.85 \AA$ |
| $\mathrm{O}(3)$ | $\mathrm{O}\left(2^{\text {vii }}\right)$ | $\mathrm{H}(2)$ | 164 | 0.90 | 2.88 |
| N | $\mathrm{O}\left(1^{\prime}\right)$ | $\mathrm{H}(3)$ | 174 | 0.95 | 3.01 |
| N | $\mathrm{O}(3)$ | $\mathrm{H}(4)$ | 175 | 0.92 | 3.02 |

The shortest $\mathrm{C}-\mathrm{C}$ distance between two different networks is $4 \cdot 17 \AA\left[C(2)-C\left(4^{\prime}\right)\right]$. For the hydrogen atoms not involved in hydrogen bonds, there is only one contact involving a distance shorter than $3.0 \AA$, that is $\mathrm{H}(8)-\mathrm{H}\left(11^{\prime}\right)=2 \cdot 67 \AA$.

## Discussion

The structural analysis of bis-(6-aminohexanoato)copper(II) dihydrate clearly shows that four ligands coordinate unidentately to the central copper atom, two of them via a carboxylate atom and the other two via a nitrogen atom (Fig. 1). Thus, the formula reported by Velicko, Kuzmina \& Ermalova (1965) is not correct; they claimed that copper is coordinated through a nine-membered chelate ring, formed by the amino nitrogen and the carboxylate oxygen atoms. Also, unidentate coordination formed by four ligands through their nitrogen atoms, as reported by Nakahara, Hidaka \& Tsuchida (1956), does not agree with
the present structure (Figs. 1 and 2). It does not seem probable that copper(II) can coordinate to the $\varepsilon$-amino nitrogen atom, in aqueous solution, unless the copper ions are first reduced and then slowly reoxidized. This is indicated from high precision e.m.f. measurements on the present system, which demonstrate that copper(II) ions only interact directly with carboxylate groups in aqueous solution (Österberg \& Toftgård, 1972). This fact is further substantiated by another copper(II)-aminohexanoate structure, where the central copper atom is coordinated via eight oxygen atoms (Österberg, Sjöberg \& Söderquist, 1970).

That the synthesis of the present crystals first requires the reduction and then the slow oxidation of copper(II) parallels the reconstitution of native $\mathrm{Cu}(\mathrm{II})-$ protein from apoprotein and copper ions. This re-

Fig. 2. Copper coordination with bond distances (in $\AA$ ). The orientation is the same as in Fig. 1.

Fig. 3. Bis-(6-aminohexanoato)copper(II) dihydrate viewed down the $b$ axis, showing the positions of the hydrogen bonds.
constitution is best achieved by the addition of $\mathrm{Cu}(\mathrm{I})$ to the apoprotein, and then subsequent oxidation (Omura, 1961). Thus, a complex involving some $\varepsilon$ amino groups may be considered as a potential structural model for those copper binding sites that readily undergo reduction and oxidation. Such a binding site having 'unidentate' ligands would allow the ligands to move independently, and thus the coordination sphere can be rearranged or changed without any serious damage to the protein. For instance, a linear copper(I) complex, kept in position by two $\varepsilon$-amino groups, situated in a somewhat hydrophobic environment, may be readily transformed into a copper(II) complex via oxidation and the simultaneous approach of two carboxylate groups.

We are grateful to Mrs Gunilla Sterner for skilful technical assistance, and to the Swedish Natural Science Research Council, the Swedish Medical Research Council, and Magnus Bergvall's fund for financial support.

# The Crystal Structure of p-Nitroacetophenone 

By J.K.S. Kim and E. R. Boyko<br>Chemistry Department, Providence College, Providence, R.I. 02918, U.S.A.<br>and G.B.Carpenter<br>Metcalf Research Laboratory, Brown University, Providence, R.I. 02912, U.S.A.

(Received 10 January 1972; accepted 19 January 1973)
$p$-Nitroacetophenone, $\mathrm{C}_{8} \mathrm{H}_{7} \mathrm{NO}_{3}$, forms monoclinic crystals in the space group $P 2_{1} / c$ with four molecules in a unit cell of dimensions: $a=10.069$ (8), $b=8.552$ (8), $c=9.094$ (8) $\AA$ and $\beta=93.85$ (1). The structure was refined by a full-matrix least-squares analysis of three-dimensional X-ray diffraction counter data to a final $R$ value of $0 \cdot 053$. The molecule can be described as planar; the molecular plane lies close to the crystallographic (202) plane. The functional groups are slightly twisted about an axis that coincides approximately with the bond from the ring to the central atom of the group.

## Introduction

A crystal structure determination of $p$-nitroacetophenone, $\mathrm{C}_{8} \mathrm{H}_{7} \mathrm{NO}_{3}$, is of chemical interest since the compound contains two electron-withdrawing groups attached in competing positions to the benzene ring. The absence of major steric interactions ensures that the aromatic bond distances and the planarities of the functional groups with respect to the benzene ring will reflect primarily the inductive and resonance effects present.

Film techniques were initially employed to determine and refine the structure. When an automatic single-crystal diffractometer became available, a new set of intensity data was collected and the final refinement was based solely on these data.

## Experimental

The compound was prepared by Dr T. T. Galkowski of Providence College. Three recrystallizations from anhydrous diethyl ether produced single crystals which
