# The Crystal Structure of $\mathbf{S r}_{2} \mathbf{S b}$ 

By M. Martinez-Ripoll, A. Haase and G. Brauer<br>Chemisches Laboratorium der Universität Freiburg, 78 Freiburg (Breisgau), Albertstrasse 21, Germany (BRD)

(Received 15 March 1973; accepted 3 April 1973)

#### Abstract

$\mathrm{Sr}_{2} \mathrm{Sb}$ crystallizes in the tetragonal system, space group $14 / \mathrm{mmm}$, with four formula units in a cell of dimensions $a=5.002 \pm 0.003$ and $c=17.405 \pm 0.008 \AA$. The calculated density is $4.528 \mathrm{~g} \mathrm{~cm}^{-3}$. The structure of $\mathrm{Sr}_{2} \mathrm{Sb}$ has been solved by three-dimensional Patterson synthesis. The positional parameters and isotropic thermal coefficients were refined by the least-squares method based on 674 reflexions. The final conventional $R$ index is 0.095 . There are uncommonly short $\mathrm{Sr}-\mathrm{Sr}$ distances in layers perpendicular to the $c$ axis.

## Introduction

Preliminary results on the $\mathrm{Sr}-\mathrm{Sb}$ system obtained by Shchukarev, Morozova \& Kan Kho-in (1957a, b) indicated the existence of four compounds in the system, $\mathrm{SrSb}_{3}, \mathrm{SrSb}, \mathrm{Sr}_{3} \mathrm{Sb}_{2}$ and $\mathrm{Sr}_{2} \mathrm{Sb}$. Later, Brauer \& Müller (1961) reported on a compound with formula $\mathrm{Sr}_{2} \mathrm{Sb}$ and tetragonal symmetry.

A recent investigation undertaken by Martinez-Ripoll \& Brauer (1973) demonstrated the existence of a new compound in the system with hexagonal symmetry, whose formula $\mathrm{Sr}_{5} \mathrm{Sb}_{3}$ was deduced from the study of its crystal structure.

The present paper reports on the crystal structure of the compound $\mathrm{Sr}_{2} \mathrm{Sb}$, whose single crystals grow together with those of $\mathrm{Sr}_{5} \mathrm{Sb}_{3}$.

## Experimental

Single crystals of $\mathrm{Sr}_{2} \mathrm{Sb}$ are prepared by the method described in the case of $\mathrm{Sr}_{5} \mathrm{Sb}_{3}$ (Martinez-Ripoll \& Brauer, 1973). The crystals of $\mathrm{Sr}_{2} \mathrm{Sb}$ are black and have laminar shape, the $c$ axis being perpendicular to the plate. Because of their extreme sensitivity to air they had to be kept under argon atmosphere.

Precession photographs taken with Mo $K \alpha$ radiation were used to determine the symmetry, space group and approximate lattice parameters. $\mathrm{Sr}_{2} \mathrm{Sb}$ was found to be tetragonal with four formula units in the cell. The systematic absences correspond to four space groups, $I 4 \mathrm{~mm}, I \overline{4} \mathrm{~m} 2, I \overline{4} 2 \mathrm{~m}$ and $I 4 / \mathrm{mmm}$. The statistics of the normalized structure factors showed the existence of a centre of symmetry; no piezoelectric properties were found and analysis of the Patterson function led to a centrosymmetric arrangement of atoms. As a consequence, the space group $14 / \mathrm{mmm}$ was assumed.

Accurate measurement on a diffractometer of the $\theta$ values for several reflexions led to the lattice parameters $a=5.002 \pm 0.003$ and $c=17.405 \pm 0.008 \AA$. The calculated density is $4.528 \mathrm{~g} \mathrm{~cm}^{-3}$. These data agree well with the results of Brauer \& Müller (1961) and Müller (1960): $a=5.00, c=17.41 \AA$ and experimental density $4.52 \mathrm{~g} \mathrm{~cm}^{-3}$.

Intensity data were measured for a complete octant of reciprocal space using a single crystal ( $0.025 \times 0.030$ $\times 0.006 \mathrm{~cm}$ ) mounted on a Weissenberg-geometry single-crystal Huber diffractometer (RHD 402) on line to a PDP-8 computer. Pulse-height analysis was used with Mo $K \alpha$ radiation in conjunction with a monochromating graphite crystal. Symmetry-related reflexions were averaged to produce 674 independent reciprocal points. All intensity data were corrected for the Lorentz-polarization factor. For the purpose of the present work absorption corrections were not considered to be necessary ( $\mu R \simeq 1 \cdot 6$ ). In any case, such corrections would be tedious because of the irregular form of the crystals.

## Determination of the structure

Structure factors based on the coordinates obtained from the three-dimensional Patterson function and isotropic temperature factors of $1.21 \AA^{2}$ gave an $R$ index of $0 \cdot 20$. The $f$ curves for neutral atoms (Thomas \& Umeda, 1957) corrected for anomalous dispersion were used.
Refinement was done by the full-matrix least-squares procedure using the program ORFLS (Busing, Martin \& Levy, 1962) and assuming unit weights. The final conventional $R$ index is 0.095 based on the parameters given in Table 1.*

## Table 1. Positional and thermal parameters

Standard deviations, multiplied by $10^{5}$, are given in parentheses.

|  | $x / a$ | $y / b$ |  | $z / c$ |
| :--- | :---: | :---: | :---: | :---: |
|  | $B$ |  |  |  |
| $\mathrm{Sr}(1)$ | 0 | $\frac{1}{2}$ | 0 | $0.85 \AA^{2}$ |
| $\mathrm{Sr}(2)$ | 0 | 0 | $0.32825(10)$ | $1 \cdot 24$ |
| Sb | 0 | 0 | $0.13666(5)$ | 0.94 |

[^0]This structure agrees with the one given by Müller (1960), who used single crystals to propose a space group. He used powder patterns to calculate by trial-and-error methods atomic parameters of the compound $\mathrm{Sr}_{2} \mathrm{Bi}$ believed to be isomorphous with the compound $\mathrm{Sr}_{2} \mathrm{Sb}$.

## Description and discussion of the structure

This crystal structure can be visualized as being built up from atomic layers perpendicular to the $\mathbf{c}$ direction, similar to those of the PbFCl structure, as shown in Fig. 1. There are layers $(A)$ containing only $\operatorname{Sr}(1)$ atoms in a cubic arrangement. Between two successive $A$ layers there are two more layers ( $B$ ), each one containing $\mathrm{Sr}(2)$ and Sb atoms. To a first approximation, the $\mathrm{Sr}(2)$ and Sb atoms in a $B$ layer form a closest-packed sheet, one of these layers being translated by a vector (a/2+ $\mathbf{b} / 2$ ) with respect to the other, in such a way that each $\mathrm{Sr}(2)$ atom has an Sb atom as nearest neighbour on the adjacent layer of the same kind. The strontium atoms of the $A$ layers, $\operatorname{Sr}(1)$, are all coplanar. However, the atoms of the $B$ layers are not exactly in the same plane; the $\operatorname{Sr}(2)$ atoms are shifted $0.61 \AA$ from the plane built up by the Sb atoms in the direction of the adjacent $B$ layer.

Each strontium atom of the $A$ layers, $\operatorname{Sr}(1)$, has twelve neighbours [ $4 \mathrm{Sr}(1)+4 \mathrm{Sr}(2)+4 \mathrm{Sb}$ ] arranged as shown in Fig. 2. The four antimony atoms are each at a distance of $3.451 \AA$ and the four $\operatorname{Sr}(2)$ atoms at 3.898 $\AA$. The other four neighbours are $\operatorname{Sr}(1)$ atoms, and their arrangement implies four very short $\operatorname{Sr}(1)-\operatorname{Sr}(1)$ distances of $3.537 \AA$.

The atomic distribution around the strontium atoms of the $B$ layers, $\operatorname{Sr}(2)$, is shown in Fig. 3. Each one of these atoms has thirteen neighbours $[4 \operatorname{Sr}(1)+4 \operatorname{Sr}(2)+$ $5 \mathrm{Sb}]$. Four Sb atoms on the same $B$ layer are situated at the corners of a square, at distances of $3.589 \AA$; the fifth antimony atom at a distance of $3.335 \AA$ belongs to the neighbouring $B$ layer and completes a pyramidal arrangement. The four $\mathrm{Sr}(1)$ atoms belong to an $A$ layer and are at $3.898 \AA$ from the $\operatorname{Sr}(2)$ atom. The remaining four neighbours of $\operatorname{Sr}(2)$ are also $\operatorname{Sr}(2)$ atoms but situated in the parallel $B$ layer and at distances appreciably greater ( $4 \cdot 464 \AA$ ).

Each antimony atom has nine neighbours only, forming a unit $\mathrm{SbSr}_{9}$ as shown in Fig. 4. Four of the neighbours are $\mathrm{Sr}(1)$ atoms, each at a distance of 3.451 $\AA$. Four $\operatorname{Sr}(2)$ atoms are at $3.589 \AA$ and one $\operatorname{Sr}(2)$ atom is at $3.335 \AA$. Each $\operatorname{Sr}(1)$ atom is shared among four $\mathrm{SbSr}_{9}$ groups and each $\operatorname{Sr}(2)$ atom is shared among five groups. A similar arrangement of strontium atoms around the Sb atom (tetrakaidecahedron) has been found in the structure of $\mathrm{Sr}_{5} \mathrm{Sb}_{3}$ (Martinez-Ripoll \& Brauer, 1973).

A list of all interatomic distances is given in Table 2. Several valence angles are reported in Table 3.
The average $\mathrm{Sb}-\mathrm{Sr}$ distance of $3.499 \AA$ is appreciably short compared with the value of $3 \cdot 70 \AA$ ob-
tained from the sum of metallic radii given by Pauling (1947) and assuming coordination numbers of 9,12 and 13 for $\mathrm{Sb}, \mathrm{Sr}(1)$ and $\mathrm{Sr}(2)$ respectively. A similar result has been found in the structure of $\mathrm{Sr}_{5} \mathrm{Sb}_{3}$ (Mar-tinez-Ripoll \& Brauer, 1973), where the mean value of

Table 2. Interatomic distances
Estimated standard deviation $\pm 0.008 \AA$

|  |  |  | Averages |  |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{Sr}(1)-\mathrm{Sb}$ | $3 \cdot 451 \AA$ | ( $\times 4$ ) | $\mathrm{Sr}(1)-\mathrm{Sr}(1)$ | 3.537 A |
| $\mathrm{Sr}(1)-\mathrm{Sr}(1)$ | 3.537 | $(\times 4)$ | $\mathrm{Sr}(1)-\mathrm{Sr}(2)$ | 3.898 |
| $\mathrm{Sr}(1)-\mathrm{Sr}(2)$ | 3.898 | $(\times 4)$ | $\mathrm{Sr}(1)-\mathrm{Sr}$ | 3.718 |
| $\mathrm{Sr}(2)-\mathrm{Sb}$ | 3.335 A | $(\times 1)$ | $\mathrm{Sr}(2)-\mathrm{Sr}(1)$ | $3.898 \AA$ |
| $\mathrm{Sr}(2)-\mathrm{Sb}$ | 3.589 | $(\times 4)$ | $\mathrm{Sr}(1)-\mathrm{Sr}(2)$ | $4 \cdot 464$ |
| $\mathrm{Sr}(2)-\mathrm{Sr}(1)$ | 3.898 | $(\times 4)$ | $\mathrm{Sr}(2)-\mathrm{Sr}$ | $4 \cdot 181$ |
| $\mathrm{Sr}(2)-\mathrm{Sr}(2)$ | 4.464 | $(\times 4)$ |  |  |
| $\mathrm{Sb}-\mathrm{Sr}(2)$ | $3.335 \AA$ | $(\times 1)$ | $\mathrm{Sb}-\mathrm{Sr}(1)$ | $3.451 \AA$ |
| $\stackrel{\mathrm{Sb}}{ }-\mathrm{Sr}(1)$ | 3.451 | $(\times 4)$ | $\mathrm{Sb}-\mathrm{Sr}(2)$ | 3.538 |
| $\mathrm{Sb}-\mathrm{Sr}(2)$ | $3 \cdot 589$ | $(\times 4)$ | $\mathrm{Sb}-\mathrm{Sr}$ | $3 \cdot 499$ |

the $\mathrm{Sb}-\mathrm{Sr}$ distances is $3 \cdot 516 \AA$. These results and the short $\operatorname{Sr}(1)-\mathrm{Sr}(1)$ distances of $3.537 \AA$ mentioned above ( $3.711 \AA$ in $\mathrm{Sr}_{5} \mathrm{Sb}_{3}$ ) indicate a pronounced deviation from metallic behaviour, probably in the direction of a partial ionic character of these atoms.

Thanks are due to Huber Diffraktions-Technik for the facilities given in order to obtain the intensity data and to the Deutsche Forschungs-Gemeinschaft for making available some laboratory equipment. All the numerical calculations were carried out on the 7040 IBM and 1108 UNIVAC computers of the University of Freiburg, Germany.

Table 3. Valence angles
Estimated standard deviation $\pm 0 \cdot 2^{\circ}$

| Around $\operatorname{Sr}(1)$ |  |  |  |
