# The Crystal and Molecular Structure of 2-Amino-4-phenylthiazole Hydrobromide Monohydrate 

By G. R.Form and E.S. Raper<br>Department of Chemistry, Newcastle-upon-Tyne Polytechnic, Newcastle-upon-Tyne, NE1 8ST, England<br>and T.C.Downie<br>School of Chemistry, Thames Polytechnic, London SE1, England

(Received 20 June 1973; accepted 2 October 1973)

#### Abstract

2-Amino-4-phenylthiazole hydrobromide monohydrate is monoclinic with $a=12 \cdot 425, b=9 \cdot 477, c=$ $10.339 \AA, \beta=110 \cdot 55^{\circ}, Z=4$. Intensities were collected ona Hilger-Watts four-circle diffractometer with Mo $K \alpha$ radiation ( $\lambda=0.7107 \AA$ ). The structure was solved by Patterson and Fourier methods and refined by full-matrix least-squares calculations. $R$ for 1094 observed reflexions was $0 \cdot 085$. The compound consists of a protonated heterocyclic molecule, a bromide ion and a water molecule. The phenyl and thiazole rings are planar (within experimental error), with an interplanar angle of $19 \cdot 1^{\circ}$ and an interring distance of $1.51 \AA$. The heterocyclic molecule is described in terms of resonance between protonated aminothiazole and protonated iminothiazoline forms, with a larger contribution from the latter. The negative charge on the bromide ion is modified by eight contacts to neighbouring atoms. Two at 3.547 and $3.722 \AA$ are to neighbouring sulphur atoms. The rest are hydrogen bonds. Two are $\mathrm{N}-\mathrm{H} \cdots \mathrm{Br}^{-}$ bonds at 3.34 and $3.64 \AA$, which are formed by symmetry-related exocyclic amino nitrogen atoms. A C-H $\cdots \mathrm{Br}^{-}$bond at $3 \cdot 64 \AA$ is formed from $\mathrm{C}(5)$ and $\mathrm{H}(5)$ atoms. Each water molecule forms three bonds to two bromide ions. Two $\mathrm{H} \cdots \mathrm{Br}^{-}$distances of 2.7 and $2.8 \AA$ involve the same bromide ion while a third $\mathrm{H} \cdots \mathrm{Br}^{-}$distance of $3 \cdot 1 \AA$ is to a symmetry-related ion. This situation suggests that one of the water hydrogen atoms is asymmetrically bifurcated.

## Introduction

2-Amino-4-phenylthiazole hydrobromide monohydrate (2-APT) reduces the corrosion rate of mild steel in $0 \cdot 1 M$ hydrochloric acid. The extent of this corrosion inhibition ranges from $30 \%$ at $0.03 \times 10^{-3} \mathrm{M}$ to $87 \%$ at the solubility limit of the inhibitor, $1 \cdot 1 \times 10^{-3}$ $M$ (Donnelly, Downie \& Grzeskowiak, unpublished). The related compound, 2-aminothiazole, also inhibits the corrosion of mild steels as well as copper alloys and is used as a brightener in the electroplating industry.

Hudson \& Warning (1970) have demonstrated that the addition of a small amount of inorganic halide together with organic molecules, such as pyrrole, to sulphuric acid solutions of low-carbon steels considerably reduces both the rate of dissolution and hydrogen absorption by the steel. It is possible that corrosion inhibition in this case is caused by coordination of the organic molecule and the halide to cations on the metal surface. Poling (1970) has provided evidence for the formation of complexes on metal surfaces by demonstrating that the corrosion inhibition of copper, in dilute sulphuric acid solution, by benzotriazole (BTZ) occurs by the formation of polymeric $[\mathrm{Cu}(\mathrm{I}) \mathrm{BTZ}]_{n}$ layers several thousand ångströms thick on the metal surface. The coordination of 2 -aminothiazole to the $\mathrm{M}^{\text {II }}$ ions of cobalt, nickel, and copper has been studied by Duff, Hughes \& Rutt (1972) who report nitrogenbonded rather than sulphur-bonded complexes for this monodentate ligand.

The coordination chemistry and structure of the inhibitor provide useful information towards the understanding of corrosion inhibition processes and the structure of 2-APT has been undertaken as part of a continuing program of work in this field.

## Experimental

## Crystal data

Anhydrous 2-APT was obtained from the Aldrich Chemical Company. Single crystals, suitable for X-ray analysis, were obtained by evaporation from aqueous ethanolic solution.

Comparison of the infrared spectra of the original and the recrystallized material indicated the retention of water following recrystallization. This was confirmed by a density determination by the flotation method.

The crystals grew as thin needles elongated along [100] and were allocated to space group $P 2_{1} / c$ from Weissenberg and precession photographic data. Unitcell dimensions were determined on a Hilger-Watts four-circle diffractometer with Mo $K \alpha(\lambda=0.7107 \AA)$ radiation (Table 1).

## Data collection and reduction

A crystal of dimensions $0.40 \times 0.23 \times 0.11 \mathrm{~mm}$, with Mo $K \alpha$ radiation and a 3.5 mm collimator, was used to collect the data on the diffractometer. A $\theta-2 \theta$ scan technique was employed out to $20=40^{\circ}$ in the $h k l$ and $\bar{h} k l$ octants. Each scan consisted of 70 steps at inter-

vals of $0.01^{\circ}$, the total counting time for each reflexion being 210 s plus 35 s for each of two background counts performed before and after the scan. The 300 , 004 and $\overline{1} 52$ reflexions were measured as internal standards every 40 reflexions. 2312 unique reflexions were measured and of these 1097 were greater than $3 \sigma$ and were considered observed.

The data were corrected for Lorentz and polarization effects but not for absorption.

## Structure determination and refinement

The coordinates of the non-hydrogen atoms were obtained by Patterson and Fourier methods and refined by least-squares calculations. In the later stages of refinement the weighting scheme used was:

$$
V \omega=1 /\left[P_{1}+\left|F_{o}\right|+P_{2}\left[\left.F_{o}\right|^{2}+P_{3}\left|F_{o}\right|^{3}\right]^{1 / 2}\right.
$$

with $P_{1}=10.8, P_{2}=0.011$ and $P_{3}=1 \times 10^{-4}$.
With $R=0.089$ a difference synthesis was calculated with only those reflexions having $\sin ^{2} 0 \leq 0 \cdot 11$. Eleven peaks ranging from 0.35 to $0.65 \AA^{-3}$ were observed and assigned to hydrogen atoms. Some residual electron density, $1.0 \mathrm{e}^{-3}$, was also observed around the bromine atom. Each hydrogen atom was given a temperature factor equal to that of the atom to which it was attached and refined isotropically. The non-hydrogen atoms were refined by full-matrix least-squares calculations to $R=0.085$. At this stage no shift was greater than one-third of the corresponding standard deviation and refinement was stopped. A weighting scheme showed that $\sum \omega \Delta^{2} / N$ was independent of both $\left|F_{o}\right|$ and $\sin ^{2} \theta$.

Atomic scattering factors for $\mathrm{Br}^{-}, \mathrm{Br}, \mathrm{S}, \mathrm{N}, \mathrm{O}$ and C were taken from Volume III of International Tables for X-ray Crystallography (1962). A dispersion correc-

tion of -0.3 e was added to the $\mathrm{Br}^{-}$and Br scattering curves (Templeton, 1962). Although calculations involving both $\mathrm{Br}^{-}$and Br were performed there were no observable differences in the coordinates of the atoms; the results quoted are for the $\mathrm{Br}^{-}$ion since this is chemically more sensible.

The scattering curve for hydrogen was that of Stewart, Davidson \& Simpson (1965). Reflexions 100, 210 and 310 were omitted from the final stages of refinement as they appeared to be subject to extinction. The final positional and thermal parameters are shown in Table 2(a) and (b) and the observed and calculated structure amplitudes in Table 3.

Table 3. Observed and calculated structure factors

## Description and discussion of the structure

Bond lengths and angles are listed in Table 4(a) and (b). Fig. 1 shows a labelled perspective drawing of the origin molecule in the unit cell. Only hydrogen atoms $\mathrm{H}(2)$ and $\mathrm{H}(5)$ are included; the remainder take the number of the atom to which they are attached; those in the water molecule are $\mathbf{H}(1)$ and $\mathbf{H}(6)$.

## (a) Planarity in the molecule

The planes of best fit for the molecule and their atomic displacements are listed in Table 5.

Both the phenyl and aminothiazole rings are planar with mean atomic displacements of 0.015 and $0.010 \AA$ respectively. The small dihedral angle of $19 \cdot 1^{\circ}$ indicates that resonance and lattice energy terms predominate. In compounds with large dihedral angles, such as the $50^{\circ}$ reported by Sabelli \& Zanazzi (1969a) in $N$-methyl-3-phenyl-4-bromoisoxazolin-5-one, potential-energy terms predominate largely because of steric hindrance between the adjacent methyl and phenyl groups. In the related $N$-methyl-4-phenylisoxazoline-5-one (Sabelli \& Zanazzi, 1969b) the dihedral angle is $12^{\circ}$.

[^0](b) Molecular dimensions

The average bond length in the phenyl ring, $1 \cdot 38$ (3) $\AA$, is within the expected range. The inter-ring distance of $1.51 \AA$ is possibly significantly different from a pure $\mathrm{C}\left(s p^{2}\right)-\mathrm{C}\left(s p^{2}\right)$ single-bond distance of $1.466 \AA$ (Brown, 1959). Lengthening of such bonds is common, however, in the presence of hetero-atoms (Kuchitsu, Fukuyama \& Morino, 1968).

Bond lengths within the thiazole ring are compared with the corresponding values from some related molecules in Table 6. Excellent agreement is observed between Fehlmann's (1970) data and those of 2-APT. A comparison of the theoretical data for the thiazole molecule with the other results in Table 6 indicates that the largest differences occur in the $\mathrm{C}-\mathrm{S}$ bond lengths, the observed values being generally the greater. Fehlmann considers the $\mathrm{C}-\mathrm{S}$ bonds in 2-methylaminobenzothiazole to be pure single bonds if shortening due to hybridization is taken into account.

The exocyclic, $\mathrm{C}(2)-\mathrm{N}(2)$, and heterocyclic, $\mathrm{C}(2)-$ $\mathrm{N}(3)$, bonds possess 60 and $40 \%$ double-bond character respectively, on Wheatley's (1955) scale. This is indicative of amino-imino tautomerism in the neutral molecule. These tautomers are illustrated in Fig. 2, together with an ionic aminothiazole form. Mornon \& Raveau (1970) report a similar tautomeric system in 2-amino-5-phenylthiazoline-4-one and suggest that approximately equal proportions of amino, imino and ionic forms are present. Tautomers I and III (Fig. 2) indicate atoms $\mathrm{N}(2)$ and $\mathrm{N}(3)$ to be likely binding sites for the proton from the HBr molecule. The location of two hydrogen atoms on $N(2)$ and one on $N(3)$, together with the significant delocalization of the $p \pi$ electrons in the $\mathrm{N}(2)-\mathrm{C}(2)-\mathrm{N}(3)$ region of the protonated molecule, indicate that it is best described in terms of the canonical forms illustrated in Fig. 3. The very short exocyclic C-N distance suggests that form II is probably the more significant.

## (c) Molecular packing and hydrogen bonding

The unit-cell contents are illustrated in $a^{*}$ projection in Fig. 4. The hydrogen bonding scheme is illustrated in Fig. 5, also in $a^{*}$ projection. Only the relevant molecules are included in this Figure and each is labelled by the symmetry code used in Table 8. The bromide ion and water molecules used are symmetry-related to those whose coordinates appear in Table 2. All the shortest non-bonding contacts are listed in Table 7 and the hydrogen-bonded distances and angles are shown in Table 8.

Table 7. Shortest ( $<4.0 \AA$ ) non-bonding intermolecular contacts in 2-APT (e.s.d.'s in parentheses)

Table 8. Hydrogen-bond distances and angles involving a bromide ion (e.s.d.'s in brackets)

The molecules are stacked head to tail along $\mathbf{c}$. There are no direct inter-ring hydrogen bonds but an extensive hydrogen-bonded network exists which involves bromide ions, amino-nitrogen atoms, $C(5)$ atoms and water oxygen atoms. It can be seen from Fig. 5 that the negative charge on the bromide ion is modified by eight contacts. There is no regular coordination about the ion, and its proximity to both the screw axis

and the glide plane is related to the large number of contacts.

The $\mathrm{S} \cdots \mathrm{Br}^{-}$distances of 3.547 and $3.722 \AA$ are shorter than the sum of the van der Waals radii, $3 \cdot 80$ (Pauling, 1960). Similar reductions, $3 \cdot 476$ and $3 \cdot 491 \AA$, have been observed by Power, Pletcher \& Sax (1970) and interpreted in terms of weak $\mathrm{S} \cdots \mathrm{Br}^{-}$interactions. Such interactions seem likely in 2-APT as part of the process of neutralizing the charge on the bromide ion. The same workers suggest a $\mathrm{C}-\mathrm{H} \cdots \mathrm{Br}^{-}$distance of $3.62 \AA$ consisting of a C-H distance of $1.64 \AA$ and a $1.98 \AA$ acceptor radius for the $\mathrm{Br}^{-}$ion. The $3.64 \AA$ for the $\mathrm{C}(5)-\mathrm{H}(5) \cdots \mathrm{Br}^{-}$contact in 2-APT is in good agreement with this computed distance and it is reasonable to classify this contact as a weak, non-linear hydrogen bond.
In hydrated halogeno organic crystals, water molecules tend to direct their hydrogen atoms toward halide ions rather than heterocyclic hydrogen-bond acceptor atoms (Clark, 1963). This preference is strong and often results in spiral chains of hydrogen-bonded water molecules. Such features are present in this structure. Each water molecule forms three hydrogen bonds to two bromide ions. The $\mathrm{H}(1) \cdots \mathrm{Br}^{-}$and $\mathrm{H}(6) \cdots \mathrm{Br}^{-}$ distances of 2.7 and $2.8 \AA$ respectively are to the same bromide ion and display significant shortening from the sum of the van der Waals radii ( $\mathrm{H}=1 \cdot 2$ and $\mathrm{Br}^{-}=$ $1.98 \AA$ ). They must be regarded as definite hydrogen bonds. The $3 \cdot 1 \AA \mathrm{H}(6) \cdots \mathrm{Br}^{-}$contact is to a symmetryrelated bromide ion and must obviously be weaker than the other two. On Donohue's (1968) classification it is a doubtful hydrogen bond. However, in the asymmetric bifurcation of hydrogen atoms, it is not uncommon for one contact to be longer than the other and for the corresponding angles to exhibit differing degrees of distortion from linearity. This situation is observed in $\mathrm{H}(6)$ with $\mathrm{H}(6) \cdots \mathrm{Br}^{-}$contacts of $3 \cdot 1$ and $2.7 \AA$ and corresponding $\mathrm{O}-\mathrm{H} \cdots \mathrm{Br}^{-}$angles of 95 and $122^{\circ}$ respectively. Consequently, it seems reasonable to classify $\mathrm{H}(6)$ as a possibly asymmetrically bifurcated hydrogen atom. The $\mathrm{O}(1) \cdots \mathrm{Br}^{-}(1)$ contacts of $3 \cdot 30$ and $3.33 \AA$ compare favourably with a series of $\mathrm{O} \cdots$ $\mathrm{Br}^{-}$values reported by Lundgren (1970) for the mono-, di- and trihydrates of hydrogen bromide.

The exocylic amino group forms $\mathrm{N}-\mathrm{H} \cdots \mathrm{Br}^{-}$bonds. Two contacts, to the same bromide ion, are formed by the amino groups from two molecules which are related by the screw axis (Fig. 5). The $\mathrm{H}(4) \cdots \mathrm{Br}^{-}$distance of $2.4 \AA$ and the $\mathrm{H}(2) \cdots \mathrm{Br}^{-}$distance of $2.6 \AA$ both show significant shortening from the sum of the corresponding van der Waals radii and must be classified as definite hydrogen bonds. The $\mathrm{N}(2) \cdots \mathrm{Br}^{-}$distances and angles are compatible with some recent data which are listed in Table 9. The observed values are not unexpected in view of the polarity of the $\mathrm{N}(2)$ atom and indicate that the protonated imino-phenyl-thiazoline form is the major contributing canonical form in this structure. The remaining non-bonded distances are of the normal van der Waals type.

#### Abstract

2-Methyl-3-phenyl-4-( $N$-methyl- $N$-hydroxy-amidin)-isoxazolin-5-one hydrobromide; Fanfani, Nunzi, Zanazzi \& Zanazzi (1972) 10-Methylisoalloxazine hydrobromide trihydrate; Trus \& Fritchie (1969) $N$-Methyl-dL-leucylglycine hydrobromide; Chandrasekharan \& Subramanian (1969) This investigation

All the calculations were performed on the IBM 360/67 computer at the University of Newcastle-uponTyne. The programs used throughout the analysis, in addition to small local programs, were from the integrated set devised for the IBM 360 by Dr F. R. Ahmed and his group at N.R.C., Ottawa, Canada. The SFLS block-diagonal refinement program, $N R C-10$, was modified for full-matrix refinement by Dr H. M. M. Shearer of Durham University.

We are grateful to the S.R.C. for the provision of a research grant to G.R. Form, and to Dr H.M.M. Shearer and the Chemistry Department, University of Durham, for the use of their diffractometer.
