# Anion Ordering in TaON: A Powder Neutron-Diffraction Investigation 

By D. Armytage and B.E.F.Fender<br>Inorganic Chemistry Laboratory, South Parks Road, Oxford OX1 3QR, England

(Received 16 October 1973; accepted 7 November 1973)
The structure of tantalum oxynitride has been determined by the profile analysis of powder neutrondiffraction data collected at $4.2^{\circ} \mathrm{K}$. The compound is monoclinic, space group $P 2_{1} / c$, with $a=4.9581$, $b=5.0267, c=5.1752 \AA$, and $\beta=99.640^{\circ}\left(4.2^{\circ} \mathrm{K}\right)$. Complete ordering of the anions occurs in alternate layers normal to the [100] direction and this ordering is consistent with calculated site potentials. Short nitrogen-nitrogen distances of 2.51 to $2.64 \AA$ are observed.

## Introduction

Two polymorphs have been reported for TaON : a red low-temperature form with a complex hexagonal structure (Buslaev, Glushkova, Ershova \& Shustorovich, 1966; Buslaev et al., 1969) which transforms at approximately $800^{\circ} \mathrm{C}$ to a green modification, first reported by Brauer \& Weidlein (1965) and Brauer, Weidlein \& Strahle (1966). The latter has a monoclinic structure and is probably isostructural with baddeleyite $\left(\mathrm{ZrO}_{2}\right)$. Mixed anion compounds, including oxyfluorides, e.g. YOF (Mann \& Bevan 1970), are often ordered in layers and oxynitrides may be similarly ordered. The difference in the neutron scattering lengths for oxygen and nitrogen allows this problem to be solved by the analysis of the diffraction profile obtained from neutron powder data.

## Experimental

TaON was prepared by a method similar to that of Brauer et al. (1966). 'Specpure' grade $\mathrm{Ta}_{2} \mathrm{O}_{5}$, supplied by Johnson Matthey Chemicals Ltd, was heated to $830^{\circ} \mathrm{C}$ in a flow of dry ammonia until the weight change, colour and X-ray Debye-Scherrer photographs indicated complete conversion to TaON according to the equation

$$
\mathrm{Ta}_{2} \mathrm{O}_{5}+2 \mathrm{NH}_{3} \rightarrow 2 \mathrm{TaON}+3 \mathrm{H}_{2} \mathrm{O}
$$

The product was analysed by reconversion to $\mathrm{Ta}_{2} \mathrm{O}_{5}$ in flowing oxygen on a thermogravimetric balance.

Two separate determinations gave compositions of $\mathrm{TaO}_{0.98 \text { (2) }} \mathrm{N}_{1.01 \text { (2) }}$ and $\mathrm{TaO}_{1.01(2)} \mathrm{N}_{0.99(2)}$. Attempts to alter the $\mathrm{O}: \mathrm{N}$ ratio on the oxygen-rich side of TaON gave a mixture of phases and Swisher \& Read (1972) report that the non-stoichiometric range of TaON extends only to the nitrogen-rich side.

A room-temperature X-ray diffractometer trace was indexed on a monoclinic unit cell and a least-squares determination of the unit-cell parameters gave $a=$ 4.9692 (3) (4.966), $b=5.0330$ (3) (5.034), $c=5 \cdot 1821$ (3) (5.185) $\AA$ and $\beta=99.682(5)^{\circ}(99.65)$ where the Brauer et al. (1966) values are in parentheses. The systematic absences ( $h 0 l, l=2 n+1 ; 0 k 0, k=2 n+1$ ) indicate the space group $P 2_{1} / c$.

Neutron-diffraction measurements were carried out on the PANDA powder diffractometer at AERE Harwell. The sample was contained in a thin-walled vanadium can which was suspended in a liquid-helium cryostat. A neutron wavelength of $1.537 \AA$ [obtained by reflexion from the (331) planes of a germanium monochromator at a take-off angle of $72^{\circ}$ ] was employed and the diffraction pattern recorded from 12 to $85^{\circ}(2 \theta)$ in steps of $0.02^{\circ}$.

## Results

The neutron-diffraction profile contained 91 reflexions consistent with $P 2_{1} / c$. Refinements were carried out by means of a least-squares comparison of observed and calculated profiles (Rietveld, 1969). The program minimizes the function $\chi^{2}=\sum_{i} w_{i}\left[y_{i}(\mathrm{obs})-1 / c y_{i}(\mathrm{calc})\right]^{2}$
where $w_{i}$ is a weighting function, $y_{i}$ the number of counts at a point $i$ in $2 \theta$ and $c$ is a scale factor. Neutron scattering lengths $b_{\mathrm{Ta}}=0.700 \times 10^{-14} \mathrm{~m}, b_{\mathrm{N}}=0.940 \times$ $10^{-14} \mathrm{~m}$ and $b_{\mathrm{O}}=0.580 \times 10^{-14} \mathrm{~m}$ (Neutron Diffraction Commission, 1972) were used. The refinement involved 12 structural variables: nine positional parameters, effective scattering lengths for the two kinds of anion site and an overall temperature factor. In a structure of this type at $4.2^{\circ} \mathrm{K}$ the temperature factors are bound to be small $\left(0 \cdot 1-0 \cdot 2 \AA^{2}\right)$ so that the assumption of a single overall $B$ is reasonable. The reliability index defined as

$$
R_{\text {profile }}(\text { weighted })=100 \frac{\sum_{i} w_{i}\left[y_{i}(\mathrm{obs})-1 / c y_{i}(\text { calc })\right]^{2}}{\sum_{i} w_{i}\left[y_{i}(\mathrm{obs})\right]^{2}}
$$

converged to a value of $12.9 \%$ after four cycles, compared with an idealized minimum of $8.9 \%$ expected from purely statistical errors.

The anion sites were assigned a mean scattering length of $0.760 \times 10^{-14} \mathrm{~m}$ and the occupation numbers refined to give the total scattering for each site. The results of the refinement are given in Table 1 and it may be seen that anion sites $A_{1}$ and $A_{2}$ are exclusively occupied by N and O respectively. The observed and calculated profiles are illustrated in Fig. 1.

An investigation of TaON by differential thermal analysis did not reveal any features below the decomposition temperature (approximately $1000^{\circ} \mathrm{C}$ under nitrogen) which suggests that the monoclinic structure is maintained to this temperature, though we cannot be certain that the anions remained fully ordered.

## Discussion

Fig. 2 is a projection on the (010) plane, showing the layer order of O and N . The coordination of tantalum

is also shown and coordinations of $\mathrm{A}_{1}$ and $\mathrm{A}_{2}$ are given in Fig. 3. Four nitrogen atoms are located on one side of the cation and three oxygens on the other and this ordered arrangement is that expected on simple electrostatic grounds. Madelung potentials for each unique site in the structure were calculated assuming integral charges for the ions. Three possible arrangements were considered: (a) random occupation of the two anion sites by $\mathrm{O}^{2-}$ and $\mathrm{N}^{3-}$, (b) preferential occupation of

$\mathrm{A}_{1}$ by $\mathrm{O}^{2-}$ and $\mathrm{A}_{2}$ by $\mathrm{N}^{3-}$ and (c) the alternative arrangement with $\mathrm{A}_{1}$ occupied by $\mathrm{N}^{3-}$ and $\mathrm{A}_{2}$ by $\mathrm{O}^{2-}$. The results of these calculations are shown in Table 2. In every case it turns out that $\mathrm{A}_{1}$ is more positive, i.e. more favourable for nitrogen occupation than $\mathrm{A}_{2}$, entirely in line with the structural findings.

| $\mathrm{~A}_{1}$ | +2.333 | +2.141 | +2.524 |
| $\mathrm{~A}_{2}$ | +1.895 | +2.088 | +1.701 |

Interionic distances and angles are summarized and compared with $\mathrm{ZrO}_{2}$ in Table 3. The detailed coordinates are close to those for monoclinic $\mathrm{ZrO}_{2}$, and the nitrogen atoms occupy virtually the same positions as $\mathrm{O}_{\mathrm{II}}$ in $\mathrm{ZrO}_{2}$ [Smith \& Newkirk (1965) notation]. The cell dimensions of $\mathrm{ZrO}_{2}$ are larger than those of TaON (a consequence of the larger radius of $\mathrm{Zr}^{4+}$ ) and therefore interatomic distances would be expected to be smaller in TaON. However, we see that the tantalumoxygen distances are in fact similar to the $\mathrm{Zr}-\mathrm{O}_{\mathrm{II}}$ values and that there is a larger contraction of the $\mathrm{Ta}-\mathrm{N}$ distances than would be predicted from the change in cell dimensions alone. This contraction implies a relative displacement of the tantalum ions towards the nitrogen layers (with a slight preference for nitrogen atom in sites $A_{1} 2$ and $A_{1} 3$ ). This effect is also seen in the separation of the metal ions. Cationcation distances across the planes of anions $\mathrm{O}_{\mathbf{I}}$ and $\mathrm{O}_{\mathrm{II}}$ differ in $\mathrm{ZrO}_{2}$ ( 3.93 and $3.46 \AA$ respectively) with the shorter distance originating from the greater concentration of anions between metal ions sandwiching the $\mathrm{O}_{\mathrm{II}}$ layer. In TaON the difference is more marked and Ta-Ta distances of $3 \cdot 90$ and $3.30 \AA$ reflect the stronger Ta-nitrogen interaction.

| (2) (3) | $103^{\circ} 1^{\prime}$ | $105^{\circ} 42^{\prime}$ |
| (3) (4) | $138^{\circ} 18^{\prime}$ | $134^{\circ} 18^{\prime}$ |
| (4) (1) | $98^{\circ} 17^{\prime}$ | $100^{\circ} 24^{\prime}$ |
| (1) (2) | $102^{\circ} 39^{\prime}$ | $103^{\circ} 54^{\prime}$ |

Errors in measurements of angles are $\pm 14^{\prime}$ for TaON and approximately $\pm 16^{\prime}$ for $\mathrm{ZrO}_{2}$.

The most striking feature of the TaON structure is the close approach of the nitrogen ions to each other. The values observed here range from 2.51 to $2.64 \AA$, compared with $3.655 \AA$ in $\mathrm{Li}_{3} \mathrm{~N}$ (Zintl \& Brauer, 1935) and $2.8 \AA$ in $\mathrm{Th}_{3} \mathrm{~N}_{4}$ (Bowman \& Arnold, 1971). The only comparable nitrogen-nitrogen separation is one of $2.66 \AA$ in $\mathrm{UN}_{2}$ reported (as a high-pressure phase) by Rundle, Baenziger, Wilson \& McDonald (1948). The distances are similar to some of the shortest observed oxygen-oxygen approaches in oxides (e.g. $\mathrm{O}-\mathrm{O}$ is $2.52 \AA$ in $\mathrm{Al}_{2} \mathrm{O}_{3}$ and $2.60 \AA$ in $\mathrm{SiO}_{2}$ ) and must arise from considerable covalency in the $\mathrm{Ta}-\mathrm{N}$ interaction.

We are grateful to Dr A. K. Cheetham for useful discussions and to Professor W. Van Gool for supplying the computer program on which the site potential calculations were based. We acknowledge the Science Research Council and AERE, Harwell, for the provision of neutron facilities and thank Mr D.H.C. Harris and members of the University Support Staff for some experimental assistance. One of us (D.A.) thanks the S.R.C. for the provision of a studentship.
