$30^{\circ}$ eine Überlappung der $p_{z}$-Orbitale erschwert ist, doch deutlich verkürzt. Der hier gefundene Bor-Phen-yl-Abstand stimmt auch recht gut mit dem der $p$-Bromphenylborsäure ( $1,54 \AA$ ) (Zvonkova \& Gluškova, 1958) sowie dem des Phenylbordichlorids ( $1,52 \AA$ ) (Coffin \& Bauer, 1955) überein. Beide Verbindungen sind ebenfalls planar gebaut. Vom durchschnittlichen C-C-Abstand mit $1,388 \AA$ sind nur geringe Abweichungen festzustellen.

Die Fig. 2 und 3 zeigen die Packung der Moleküle in der Zelle. Das ganze Molekül steht senkrecht zur Spiegelebene und ist weitgehend planar, lediglich die beiden Ringebenen des Benzodioxaborols schliessen einen Winkel von $177,5^{\circ}$ ein. Die Molekülsymmetrie ist $m\left(C_{s}\right)$; die Abweichung von der höheren Symmetrie $m m\left(C_{2 v}\right)$ ist jedoch nur gering. Die Packung der Moleküle erscheint sinnvoll, denn der senkrechte Abstand zwischen zwei übereinanderliegenden Molekülen entspricht mit $3,5 \AA$ gerade der doppelten van der Waalschen Dicke von Aromaten. Der kürzeste Abstand
eines Boratoms zu einer Benzolebene ist mit $3,36 \AA$ zu gross, um eine Wechselwirkung zu erlauben.

Die Deutsche Forschungsgemeinschaft und der Fonds der Chemischen Industrie unterstützten diese Arbeit mit Sachmitteln.

## Redetermination of the $\mathbf{A l}_{\mathbf{2}}\left(\mathbf{W O}_{4}\right)_{3}$ Structure

By J.J.de Boer<br>Koninklijke/Shell-Laboratorium, Amsterdam (Shell Research B.V.), The Netherlands

(Received 4 March 1974; accepted 26 March 1974)

#### Abstract

Al}_{2}\left(\mathrm{WO}_{4}\right)_{3}\), orthorhombic, $\mathrm{Pbcn}, 4$ formula units in the cell, $a=12.574$ (5), $b=9.045$ (4), $c=$ $9 \cdot 121(4) \AA,\left(20^{\circ} \mathrm{C}\right)$, forms colourless, transparent crystals. Atomic parameters, except for the $z$ coordinate of $\mathrm{O}(2)$ and some temperature factors, are not significantly different from those found by Craig \& Stephenson [Acta Cryst. (1968). B24, 1250-1255] but are more precisely determined.

Introduction. The $\mathrm{Al}_{2}\left(\mathrm{WO}_{4}\right)_{3}$ crystals were prepared by J. Gaaf of this Laboratory by heating a mixture of $\mathrm{WO}_{3}$ and $\mathrm{Al}_{2} \mathrm{O}_{3}$ (in a molar ratio of 3:1) for 70 h at $1100^{\circ} \mathrm{C}$.

Systematic absences, from precession photographs, were: $h k 0, h+k=2 n+1 ; h 0 l, l=2 n+1$; and $0 k l, k=$ $2 n+1$. A triangular prismatic crystal, dimensions $0.1 \times 0.1 \times 0.5 \mathrm{~mm}$, was mounted with [010] coin-

[^0]cident with the $\varphi$ axis, on a Nonius automatic diffractometer. Cell dimensions were calculated from the $\theta$, $-\theta$ settings of 15 low-order reflexions $\left(0 \cdot 23 \AA^{-1} \leq\right.$ $\sin \theta / \lambda \leq 0.33 \AA^{-1}$ ).

In the range $0 \leq \sin \theta \mid \lambda \leq 0.59 \AA^{-1} 683$ reflexions, out of a possible number of 928 , were observed, with a $\theta-20$ scan, Zr -filtered Mo $K$ radiation, a scintillation counter and pulse-height discrimination. A reflexion was considered to be observed when $\frac{1}{2} I \geq \sigma(I)=$ $\left[C+B_{1}+B_{2}+(0.08 I)^{2}\right]^{1 / 2}$, in which $C$ is the total integrated count, $B_{1}$ and $B_{2}$ are the backgrounds measured

[^1]at each side of the scan for half the scan time, and $I=$ $C-B_{1}-B_{2}$ is the net count.
An experimental azimuth-dependent absorption correction was derived (Furnas, 1966) from azimuthal scans of the $0 k 0$ reflexions ( $k=2,4, \ldots, 10$ ). This correction and the $\theta$-dependent absorption correction for a spherical crystal with $\mu R=1 \cdot 4$ (Weber, 1969), together with the normal Lorentz-polarization correction were applied to the data set. Structure amplitudes were obtained on a common arbitrary scale.

The full-matrix least-squares refinement [function minimized: $\sum \omega\left(\left|F_{o}\right|-\left|F_{c}\right|\right)^{2}$, where $\left.\omega=1 / \sigma^{2}\left(F_{o}\right)\right]$ started from the $\mathrm{Sc}_{2}\left(\mathrm{WO}_{4}\right)_{3}$ parameters (Abrahams \& Bernstein, 1966) and, with isotropic temperature factors, resulted in a conventional $R$ (based on $F$, observed reflexions only) of $0.078, R_{w}=0.092=\left[\sum \omega\left(\left|F_{o}\right|-\left|F_{c}\right|\right)^{2} /\right.$ $\left.\sum \omega\left(F_{o}\right)^{2}\right]^{1 / 2}$. Inclusion of Zachariasen's (1968) extinction parameter reduced $R$ to 0.062 and $R_{w}$ to 0.079 . Introduction of anisotropic temperature factors for the tungsten atoms yielded the final values: $R=0.047$, $R_{w}=0.057$; error in an observation of unit weight $=$ $1 \cdot 18$. Weighting analyses based on ranges of $\sin \theta / \lambda$ and of $F_{o}$ indicated the weighting scheme to be correct. Allowance for anisotropic motion of the other atoms gave no significant improvement. Throughout the refinement neutral atomic scattering factors were used; those for Al were taken from International Tables for X-ray Crystallography (1962), those for O and W from the tables of Cromer \& Waber (1965) and the anomalous dispersion terms of $W$ were taken from those of Cromer (1965).

The final parameters are listed in Table 1. The atomic numbering scheme used is that of Abrahams \& Bernstein. For comparison the scheme of Craig \& Stephenson ( $\mathrm{C} \& \mathrm{~S}$ ) is also given. Since the latter workers used a different origin, the operation $x, \frac{1}{2}-y, z$ should be applied to their final coordinates.*

[^3]Discussion. The structure determination was undertaken since the estimations of the Al coordination which could be derived from the $\mathrm{Sc}_{2}\left(\mathrm{WO}_{4}\right)_{3}$ structure (Abrahams \& Bernstein, 1966) were not sufficiently precise. It was only after the refinement was started that we learned of the work of C \& S based on Weissenberg data. Since diffractometer data are likely to yield more precise results than photographic data, it was decided to continue the calculations.

The cell dimensions calculated agree within experimental error with those obtained by C \& S and those found by Trunov, Lutsenko \& Kovba (1967). A comparison of the atomic parameters of the two structure determinations shows that the e.s.d.'s obtained in this work are about half those reported by C \& S. Furthermore, all atomic coordinates do not differ by more than three times the e.s.d.'s obtained by C \& S except for $\mathrm{O}(1)$ [this work: $z=0.091$ (2), $\mathrm{C} \& \mathrm{~S}: z=0.058$ (7)]. This difference could be due to some disorder in the crystal used by $C \& S$, which would also be consistent with the high temperature factor of 2.7 (8) $\AA^{2}$ found by them for this atom. The $O(1)$ position determined in the present structure results in a much smaller spread in the comparable interatomic distances and angles (see Tables 2 and 3).

The author wishes to thank Mr J. Gaaf for preparing the crystals and Dr D. Bright for his helpful remarks.

# Cadmium(II) Formate Dihydrate 

By Michael L. Post* and James Trotter<br>Department of Chemistry, University of British Columbia, Vancouver 8, B.C., Canada

(Received 11 April 1974; accepted 16 April 1974)

#### Abstract

C}_{4} \mathrm{H}_{12} \mathrm{O}_{12} \mathrm{Cd}_{2}\), monoclinic, $P 2_{1} / c, a=8.982$ (4), $b=7.391(6), c=9 \cdot 760(3) \AA, \beta=97 \cdot 32(3)^{\circ}, Z=2, D_{x}$ $=2.44 \mathrm{~g} \mathrm{~cm}^{-3}$. As previously reported [Osaki, Nakai \& Watanabé (1964). J. Phys. Soc. Japan, 19, 717-723] the structure is isomorphous with the formates of manganese, zinc and copper, and forms a three-dimensional polymer. There are two formate ligands, exhibiting anti-anti and anti-syn configurations, linking together cadmium atoms which are arranged in facecentred positions in the cell. The polymer is further strengthened by hydrogen bonds between coordinated water molecules and formate oxygen atoms. $\mathrm{Cd}-\mathrm{O}$ distances vary between $2 \cdot 243(5)$ and $2 \cdot 326(5) \AA$.

Introduction. Cadmium(II) formate was prepared by dissolving finely divided $\mathrm{CdCO}_{3}$ in a slight excess of aqueous formic acid, and crystallized from aqueous

^[ * Present address: University Chemical Laboratory, Lensfield Road, Cambridge CB2 1EW, England. ]

solution as colourless parallelepipeds. Accurate cell dimensions were obtained from a least-squares treatment of the $2 \theta$ values of 16 reflexions measured on a General Electric XRD 6 diffractometer. Systematic absences were $h 0 l$ with $l$ odd, $0 k 0$ with $k$ odd; space group $P 2_{1} / c$. For data collection, a crystal of size approximately $0.20 \times 0.20 \times 0.15 \mathrm{~mm}$ was mounted with b coincident with the instrument $\varphi$ axis and all reflexions with $2 \theta \leq 55^{\circ}$ measured with Zr -filtered Mo $K \alpha$ radiation and the $\theta-2 \theta$ scan technique at a speed of $2^{\circ} \mathrm{min}^{-1}$ in $2 \theta$. Of a total 1456 observations, 890 had $I>3 \sigma$ where $\sigma^{2}(I)=S+B+(0 \cdot 06 S)^{2} \quad(S=$ scan count, $B=$ background) and were used in the structural refinement. Initial coordinates for the refinement were those of the isomorphous manganous formate dihydrate (Osaki, Nakai \& Watanabé, 1964), and after three cycles with isotropic thermal parameters $R$ was 0.099 . Refinement was continued with anisotropic thermal parameters, and after two cycles $R$ was $0 \cdot 065$. At this stage a difference synthesis indicated sites for all the hydrogen
