Discussion. There are three independent imidazole ligands: $A, B$ and $C$. The atomic numbering of the ligand is indicated in Fig. 1. Fig. 2 is a stereoscopic projection of one molecular unit. Geometric entities are given in Table 3. The Ni ion is octahedrally surrounded by six imidazole ligands. Contrary to the results of earlier investigations on metal(II) hexakis(imidazole) cations (Santoro, Mighell, Zocchi \& Reimann, 1969; Mighell \& Santoro, 1971; Strandberg \& Lundberg, 1971) no threefold axis is present. The geometry of the cation, however, shows only very slight deviations from the ideal $\overline{3}$ symmetry. No significant differences in bond distances and angles with respect to reported values and to those of imidazole (MartinezCarrera, 1966) are found. The cations are surrounded by 12 anions, the shortest anion-cation contacts being $\mathrm{F}(1)-\mathrm{N}\left(B 4\right.$ at $\left.\bar{x}+\frac{1}{2}, y-\frac{1}{2}, \bar{z}+\frac{1}{2}\right) 3 \cdot 04 \AA, \mathrm{~F}(2)-\mathrm{N}(A 4$ at $\bar{x}+1, \bar{y}+1, \bar{z}+1) 2 \cdot 81 \AA$ and $\mathrm{F}(3)-\mathrm{N}(C 4$ at $x+1, y$, $z+1) 3.03 \AA$. Each anion is surrounded by six cations. The shortest cation-cation contact is $\mathrm{C}(B 3)-\mathrm{C}(C 3$ at $\left.x+\frac{1}{2}, \bar{y}+\frac{1}{2}, z-1\right) 3 \cdot 50 \AA$. The very large temperature parameters of the fluoroborate anion are not unusual in hexasolvated coordination compounds in which the anions are very weakly bonded to the cations.

This investigation has been undertaken to support the study of e.p.r. spectra of hexasolvated metals of the first transition series. Reedijk \& Nieuwenhuyse (1972) described powder-e.p.r. spectra of these compounds and the single-crystal spectra are the subject of investigation at our laboratory (Vermaas, 1975).

All calculations were performed on the IBM 370/158 computer of the University of Leiden with programs
developed in our laboratory, partially based on ORFLS (Busing \& Levy, 1962) and ORTEP (Johnson, 1965).

This investigation was supported by the Foundation for Investigations by means of X-Ray and Electron Diffraction (FOMRE) with financial aid from the Netherlands Organization for the Advancement of Pure Research (ZWO).

# $\boldsymbol{\beta}$-Tetraphosphorus Pentasulphide 

By Alison M. Griffin and George M. Sheldrick<br>University Chemical Laboratory, Lensfield Road, Cambridge CB2 1EW, England

(Received 4 July 1975; accepted 7 July 1975)

#### Abstract

P}_{4} \mathrm{~S}_{5}\), monoclinic, $P 2_{1} / m, a=6 \cdot 389$ (3), $b=$ 10.966 (5), $c=6.613$ (3) $\AA, \beta=115.65$ (6) ${ }^{\circ}, U=417.66$ $\AA^{3}, Z=2, D_{x}=2.26 \mathrm{~g} \mathrm{~cm}^{-3}$. The structure of a new isomer has been determined by direct methods and refined to an $R$ of 0.029 for 581 unique diffractometer data. The molecular geometry is analogous to that in $\mathrm{As}_{4} \mathrm{~S}_{5}$, but quite unlike that in $\alpha-\mathrm{P}_{4} \mathrm{~S}_{5}$ and $\mathrm{P}_{4} \mathrm{Se}_{5}$. The cage structure possesses approximate mm symmetry, and consists of two PPSPS rings fused with two (PS) $3_{3}$ rings. Mean bond lengths (corrected for libration) and angles for $m m$ symmetry are: P-S, $2 \cdot 117$ (4), $2 \cdot 116$ (3), $2 \cdot 130$ (4); P-P, 2.295 (5) Å; P-S-P, $115 \cdot 5$ (2), $105 \cdot 4$ (1); S-P-S, $97 \cdot 6$ (2), $107 \cdot 4$ (1), $104 \cdot 6$ (1); S-P-P, $102 \cdot 2$ (2) ${ }^{\circ}$.

Introduction. Fourier transform ${ }^{31} \mathrm{P}$ n.m.r. studies (Griffin \& Sheldrick, 1976) have recently established the existence of several new molecular phosphorus sulphides. Two isomers of formula $\mathrm{P}_{4} \mathrm{~S}_{5}$ were found; $\alpha-\mathrm{P}_{4} \mathrm{~S}_{5}$ gives an ABCX spectrum consistent with the reported structure (Vos, Olthof, van Bolhuis \& Botterweg, 1965), and the new isomer $\beta$ - $\mathrm{P}_{4} \mathrm{~S}_{5}$ gives an $\mathrm{A}_{2} \mathrm{X}_{2}$ spectrum consistent with the structure reported here.

Crystals were obtained as elongated golden yellow platelets by cooling of a solution in $\mathrm{CS}_{2}$. Intensities were determined with an automated Syntex $P 2_{1}$ fourcircle diffractometer, $\mathrm{Cu} K \alpha$ radiation and graphite
monochromator. 1639 reflexions were measured; after application of Lp and absorption corrections, equivalent reflexions were averaged to give 581 unique reflexions with $F>2 \cdot 5 \sigma(F)$ based on counting statistics. Cell dimensions were obtained from diffractometer measurements of 15 reflexions. The structure was solved by multisolution $\sum_{2}$ sign expansion in the space group $P 2_{1} / m$; the choice of $P 2_{1} / m$ rather than $P 2_{1}$ was confirmed by the successful refinement of the structure. The structure was refined by full-matrix least-squares calculations, with anisotropic atoms, complex neutral atom scattering factors, and the weighting scheme $w=1 /\left[\sigma^{2}(F)+0 \cdot 0002 F^{2}\right]$ to a final $R^{\prime}=\sum w^{1 / 2} \triangle / \sum w^{1 / 2}\left|F_{o}\right|$ of 0.031 ; the corresponding unweighted $R$ was $0 \cdot 029$. An isotropic extinction parameter $x$ refined to $256(34) \times 10^{-8}$, where $F_{c}$ is multiplied by $\left[1-x\left|F_{c}\right|^{2} / \sin \theta\right]$. The results of the final least-squares cycle are given in Tables 1 and 2, and the derived interatomic distances and angles in Tables 3-5.*

Discussion. In $P 2_{1} / m$ the molecule must possess a crystallographic mirror plane; $\mathrm{P}(1), \mathrm{P}(2)$ and $\mathrm{S}(1)$ are found to lie in special positions in this plane. To a good approximation, the molecule possesses mm

symmetry. The anisotropic temperature factors were found to be in excellent agreement with the rigid-body motion model of Schomaker \& Trueblood (1968): $R_{g}=\left[\sum \Delta^{2} / \sum U_{i j}^{2}\right]^{1 / 2}$ for the agreement between the observed and calculated $U_{i j}$ was 0.028 . Librational tensors, with respect to axes parallel to $x^{*}, y$ and $z$,

were: $L_{11} 51(2), L_{12} 0, L_{13}-1(1), L_{22} 10(1), L_{23} 0$, $L_{33} 37(1) 10^{-4} \mathrm{rad}^{2} ; S_{11} 0(2), S_{12} 4(1), S_{13} 0(1), S_{21}$ 4(1), $S_{22} 0(2), S_{23} 5(1), S_{31} 0(1), S_{32} 5(1), S_{33} 0(1)$ $10^{-4} \mathrm{rad} \AA ; T_{11} 165(4), T_{12} 0, T_{13} 23(3), T_{22} 252(4)$, $T_{23} 0, T_{33} 219(4) 10^{-4} \AA^{2}$ (relative to an origin at $x=$ $0.4805, y=0.2500, z=0.7421$ which makes $S$ symmetric). These values were used in calculating the librationally corrected bond lengths given in Table 3 and Fig. 1.

The molecular geometry is quite unlike the rather asymmetric structure found for $\mathrm{P}_{4} \mathrm{Se}_{5}$ (Penney \& Sheldrick, 1971) and $\alpha-\mathrm{P}_{4} \mathrm{~S}_{5}$. On the other hand $\beta-\mathrm{P}_{4} \mathrm{~S}_{5}$ has the same molecular symmetry, space group, and number of atoms in special positions as $\mathrm{As}_{4} \mathrm{~S}_{5}$ (Whitfield, 1973), but the crystallographic mirror plane in $\mathrm{As}_{4} \mathrm{~S}_{5}$ lies through the atoms corresponding to $\mathrm{P}(3)$, $\mathrm{P}\left(3^{\prime}\right)$ and $\mathrm{S}(1)$, i.e. it is at right angles to the crystallographic mirror plane in $\beta-\mathrm{P}_{4} \mathrm{~S}_{5}$. The result is that the cell dimensions and atomic coordinates are quite different in the two structures. The structure of $\beta-\mathrm{P}_{4} \mathrm{~S}_{5}$ may be derived from that of $\mathrm{P}_{4} \mathrm{~S}_{7}$ (Vos et al., 1965) by removing both terminal atoms (attached to $P(1)$ and $P(2)$ in the $\beta-\mathrm{P}_{4} \mathrm{~S}_{5}$ notation). The valence angles at $\mathrm{P}(1)$ and $\mathrm{P}(2)$ are $2-5^{\circ}$ smaller in $\beta-\mathrm{P}_{4} \mathrm{~S}_{5}$ than in $\mathrm{P}_{4} \mathrm{~S}_{7}$ (consistent with lone pair-bond pair repulsion); the valence angles at S are $3-5^{\circ}$ larger in $\beta-\mathrm{P}_{4} \mathrm{~S}_{5}$ to
compensate, resulting in the unusually large value of $115.5(2)^{\circ}$ for $\mathrm{P}(1)-\mathrm{S}(1)-\mathrm{P}(2)$ in $\beta-\mathrm{P}_{4} \mathrm{~S}_{5}$. Ignoring libration, the $\mathrm{P}-\mathrm{P}$ bond in $\beta-\mathrm{P}_{4} \mathrm{~S}_{5}$ is 0.042 (7) $\AA$ shorter than the remarkably long $\mathrm{P}-\mathrm{P}$ bond in $\mathrm{P}_{4} \mathrm{~S}_{7}$, whereas the bonds between bridging $S$ and $P(1)$ and $P(2)$ are an average of $0.024 \AA$ longer in $\beta-\mathrm{P}_{4} \mathrm{~S}_{5}$.

We are grateful to the Science Research Council for a contribution towards the cost of the diffractometer, and for a maintenance grant to A.M.G. The calculations were performed on the Cambridge University IBM 370/165 computer with programs written by G.M.S.

# Trimethyllead Acetate 

By George M.Sheldrick and Robin Taylor<br>University Chemical Laboratory, Lensfield Road, Cambridge CB2 1EW, England

(Received 4 July 1975; accepted 7 July 1975)

#### Abstract

C}_{5} \mathrm{H}_{12} \mathrm{O}_{2} \mathrm{~Pb}\), orthorhombic, Pnma, $a=$ 10.77 (2), $b=7.82$ (2), $c=9.58$ (2) $\AA, U=807 \AA^{3}, Z=4$, $D_{x}=2.56 \mathrm{~g} \mathrm{~cm}^{-3}$. Trimethyllead acetate is isostructural with the analogous Sn compound; planar trimethyllead groups are linked by bridging acetate groups to form infinite chains along a, with approximately trigonal bipyramidal coordination of Pb . The two $\mathrm{Pb}-\mathrm{O}$ distances are significantly different [2.327 (24) and $2 \cdot 555(25) \AA$ ]. Other mean distances and angles are: $\mathrm{Pb}-\mathrm{C}, 2 \cdot 181$ (25); $\mathrm{C}-\mathrm{O}, 1 \cdot 223$ (30); C-C, $1 \cdot 519$ (36) $\AA$; $\mathrm{O}-\mathrm{Pb}-\mathrm{O}, \quad 169.7(8) ; \quad \mathrm{O}-\mathrm{C}-\mathrm{O}, \quad 121 \cdot 5(24) ; \quad \mathrm{O}-\mathrm{C}-\mathrm{C}$, $119.3(20)^{\circ}$. The structure was refined to an $R$ of 0.052 for 420 unique diffractometer data.

Introduction. X-ray crystallographic studies of many apparently tetravalent organotin derivatives $[e . g$. $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{SnO}_{2} \mathrm{CCH}_{3}$ (Chih \& Penfold, 1973),

$\left(\mathrm{CH}_{3}\right)_{3} \mathrm{SnOCH}_{3}$ (Domingos \& Sheldrick, 1974) and $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{SnNCO} .\left(\mathrm{CH}_{3}\right)_{3} \mathrm{SnOH}$ (Hall \& Britton, 1972)] have established the tendency of Sn to increase its coordination number above four. It is likely that this tendency is continued in the structural chemistry of organolead derivatives, but apart from the structure of $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{2} \mathrm{PbCl}_{2}$ (Mammi, Busetti \& Del Pra, 1967) and the incomplete investigations of $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{PbCN}$ (Chow \& Britton, 1971) and $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{~Pb}(\mathrm{CN})_{2}$ (Konnert, Britton \& Chow, 1972) there is little crystallographic evidence to confirm this.

Colourless crystals were obtained by recrystallization of a commercial sample of trimethyllead acetate from a methanol/acetone mixture, and were mounted in Lindemann glass capillary tubes. Most proved unsuitable for structural work, but data were eventually collected from two crystals $0.16 \times 0.07 \times 0.09 \mathrm{~mm}$
