

marginally longer than the O $\cdots$ N distance of 2.742 (3) Å found in 6-chloro-2-hydroxypyridine. The bond is effectively linear with an O-H $\cdots$ N angle of 170 (8) $^\circ$ . It is to be noted that this compound as well as the 6-chloro-2-hydroxypyridine molecule (Kvick & Olovsson, 1968; Almlöf, Kvick & Olovsson, 1971) is found in the enol form. This contrasts to the keto forms found in the crystal structures of 2-pyridone (Almlöf, Kvick & Olovsson, 1971) and 5-chloro-2-pyridone (Kvick & Booles, 1972). The preference for the enol forms in the  $\alpha$ -halogenated compounds can be explained by the electron-withdrawing properties of the halogen atoms (Katritzky, Rowe & Roy, 1967).

I thank Professor Ivar Olovsson for the facilities he has placed at my disposal. I am also indebted to Mr H. Karlsson for his invaluable technical assistance. This work has been supported by grants from the Tricentennial Fund of the Bank of Sweden and the Wallenberg Foundation, which are hereby gratefully acknowledged.

### Hydrogen Bond Studies. CI. A Neutron Diffraction Study of 2-Amino-5-chloropyridine\*

By ÅKE KVICK†

Institute of Chemistry, University of Uppsala, Sweden

AND ROBERT THOMAS AND THOMAS F. KOETZLE

Chemistry Department, Brookhaven National Laboratory, Upton, New York 11973, U.S.A.

(Received 12 May 1975; accepted 9 June 1975)

A neutron diffraction study of 2-amino-5-chloropyridine has been carried out. Intensities of 2631 reflexions were measured at the Brookhaven National Laboratory High Flux Beam Reactor and were used in subsequent refinements of the structure to an  $R(F^2)$  of 0.060. The molecules link via N-H $\cdots$ N hydrogen bonds [H $\cdots$ N 2.051 (3) Å] to produce centrosymmetric, cyclic dimers which, in turn, pack in a herring-bone formation. Information on the asphericity of the electron-cloud distribution has been obtained by the X-N technique using previous X-ray data and the present neutron data. Valence electron accumulation in the middle of covalent bonds and in expected lone-pair electron regions is found. The bond distances between heavy atoms are determined to a precision of 0.001 Å; the corresponding value for heavy atom–hydrogen atom bond lengths is 0.003 Å or better.

#### Introduction

A neutron diffraction study of 2-amino-5-chloropyridine has been carried out in order to determine

precise H atom positions and to examine the hydrogen-bonding scheme in the crystal. The X-ray structure determination of 2-amino-5-chloropyridine has been reported earlier by Kvick & Backéus (1974), and the atomic parameters determined by neutron diffraction were used together with the X-ray data to produce X-N difference-Fourier syntheses. Information on the asphericity of the electron-cloud distribution around

\* Research performed partly under the auspices of the U.S. Energy Research and Development Administration.

† Recipient of a travel grant from the Swedish Natural Science Research Council.

the atomic nuclei can thus be obtained. The theory of X-N syntheses has been given by Coppens (1974), and a comparison of the X-N technique with *ab initio* calculations has been reported by Almlöf, Kvick & Thomas (1974). This work is part of a series of systematic studies of model compounds for biologically important molecules presently being undertaken at the Institute of Chemistry, University of Uppsala.

### Crystal data

2-Amino-5-chloropyridine,  $C_5H_3N(NH_2)Cl$ . F.W. 128.562. Monoclinic,  $a=13.4370$  (6),<sup>†</sup>  $b=5.7963$  (5),  $c=7.5123$  (6) Å,  $\beta=105.512$  (6) $^\circ$ ,  $V=563.78$  Å $^3$  at 24°C.  $Z=4$ ,  $D_x=1.514$  g cm $^{-3}$ . Space group  $P2_1/c$  (Kvick & Backéus, 1974).

### Experimental

Crystals of 2-amino-5-chloropyridine suitable for neutron diffraction were grown from chloroform. A rhombohedral crystal bounded by seven faces of the forms {100}, {011} and {001}, and with a volume of 11.64 mm $^3$ , was used for the data collection.

Neutron diffraction data were collected at room temperature (+24°C) on an automated four-circle diffractometer at the Brookhaven National Laboratory High Flux Beam Reactor using the Multiple Spectrometer Control System (Beaucage, Kelley, Ophir, Rankowitz, Spinrad & van Norton, 1966).

Intensities of Bragg reflexions were measured by the  $\theta/2\theta$  step-scan technique. The scan length was varied according to the formula:  $\Delta 2\theta=k(1+8 \tan \theta)^\circ$  with  $k=1.2$  out to  $d^*=0.5$  and  $k=1.4$  for the remaining data; the step size was chosen to give approximately 40 points in each scan. Data were collected over a complete hemisphere of reciprocal space out to  $\sin \theta/\lambda=0.664$  Å $^{-1}$  ( $\lambda=1.0147$  Å). Two standard reflexions were measured at regular intervals to provide a check on the crystal and electronic stability. The variations observed in the intensities did not call for any corrective measures.

Background corrections were made by a method (Lehmann & Larsen, 1974) which separates the peak and the background in such a way that  $\sigma(I)/I$  is minimized.  $I$  is the integrated intensity and  $\sigma(I)$  its e.s.d. based on counting statistics. Squared structure amplitudes were obtained as  $F_o^2=I \sin 2\theta$  and were corrected for absorption by the Gaussian integration method using a grid of 216 points. The crystal shape was represented by the seven rational boundary planes. The linear absorption coefficient was calculated assuming the incoherent scattering cross section for H to be 40 barns and using the values of true absorption cross sections for coherent scattering of Cl, C, N and H tabulated in *International Tables for X-ray Crystallog-*

*raphy* (1962). The transmission factors fall in the range, 0.689 to 0.753 ( $\mu=1.580$  cm $^{-1}$ ).

3035 observed intensities were measured. The observed  $F_o^2$  values for each standard reflexion were averaged together but symmetry-related reflexions were not since anisotropic extinction was found to be present. Removal of systematically absent reflexions left 2631 observations upon which to base the least-squares refinements.

### Structure refinement

The starting parameters for refinement of the structure of 2-amino-5-chloropyridine were the final parameters from the X-ray analysis by Kvick & Backéus (1974). The structure was refined with the full-matrix least-squares program CLINUS. The function minimized was  $\sum w(F_o^2 - |F_c|^2)^2$ . Each reflexion was assigned a weight  $w$ , inversely proportional to the estimated variance of the observation:

$$w^{-1} = \sigma_c^2(F_o^2) + (kF_o^2)^2 = \sigma^2(F_o^2)$$

where  $\sigma_c(F_o^2)$  is based on counting statistics and  $k=0.02$  in the final cycles of refinement. The standard deviation of an observation of unit weight was:

$$S=[\sum w(F_o^2 - |F_c|^2)^2/(m-n)]^{1/2} = 1.13$$

where  $m$  is the total number of observations and  $n$  is the number of parameters varied.

Table 1. *Atomic coordinates and neutron scattering lengths*

Parameters from the present neutron study are found on the first line followed by the parameters from the X-ray study on the second line.

<sup>†</sup> Numbers in parentheses here and throughout this paper are the estimated standard deviations in the least significant digits.

In the final cycles of refinement 39 positional and 78 anisotropic thermal parameters, one scale factor, six anisotropic secondary extinction components and the neutron scattering lengths for the two N atoms were refined. In order not to bias the refinement all reflexions, even those with  $F_o^2 < 0$ , were included in the refinement. The final agreement indices are:  $R = \sum |F_o^2 - |F_c|^2| / \sum |F_o|^2 = 0.060$  and  $R_w = [\sum w |F_o^2 - |F_c|^2|^2 / \sum w F_o^2]^{1/2} = 0.062$ .

The corresponding conventional  $R(F)$  is 0.033 if the 937 reflexions with  $F_o^2 < 3\sigma_c(F_o^2)$  are excluded from the calculations.

Three different trial models were used to correct for the secondary extinction. The corrections used were those appropriate for isotropic extinction, secondary extinction for type I crystals, and secondary extinction for type II crystals. A physical interpretation of the extinction parameters is given by Coppens & Hamilton (1970). In the present case the mosaic-spread-dominated type I model gave  $R$  indices considerably lower than for the remaining two models. Consequently anisotropic extinction parameters for a type I crystal were refined in the last cycles of refinements. The refinements were based on a non-averaged data set since the extinction components are not equal for the equivalent forms of a reflexion.

The neutron scattering factors were taken to be  $\bar{b}_{Cl} =$

0.9584,  $\bar{b}_C = 0.6626$  and  $\bar{b}_H = -0.3723$  ( $\text{all} \times 10^{-12} \text{cm}$  (Shull, 1971). The values for the N atoms were obtained from the refinement and are listed in Table 1. It is reassuring that the individual scattering lengths for the N atoms were determined to be nearly identical although no constraints were included in the refinement. The scattering lengths for the N atoms were refined because several recent refinements have indicated that values lower than  $\bar{b}_N = 0.94$  (Bacon, 1972) should be used (Kvick, Koetzle, Thomas & Takusagawa, 1974).

The refined atomic parameters and scattering lengths are given in Table 1 and the refined anisotropic thermal and extinction parameters in Table 2. The scale factor used in the calculation of the X-N difference synthesis was obtained from one cycle of least-squares refinement using the X-ray data, the atomic parameters from the neutron study and spherical X-ray scattering factors.

The calculations were carried out on the CDC 6600 computers at Brookhaven National Laboratory and on the IBM 370/155 and 1800 computers in Uppsala.

#### Comparison of neutron and X-ray parameters

Atomic positional and thermal parameters from the neutron and X-ray studies are compared in Tables 1 and 2. As expected a close agreement is generally found

Table 2. Anisotropic thermal ( $\times 10^5$ ) and extinction ( $\times 10^2$ ) parameters

The parameters from the neutron study are followed on the second line by the parameters from the X-ray refinement. The anisotropic thermal parameters are of the form  $\exp \{-(\beta_{11}h^2 + \dots + 2\beta_{12}hk + \dots)\}$ .

between the non-hydrogen atom parameters; significant differences do arise however for some of the atoms. The H atom parameters show a characteristic disparity resulting from the asphericity of the electron distribution associated with these atoms. A tendency for higher thermal parameters in the X-ray case can be noticed.

### Description and discussion of the structure

The 2-amino-5-chloropyridine molecules exist in the amino form and are linked to produce dimers *via* pairs of N-H $\cdots$ N hydrogen bonds [H $\cdots$ N = 2.051 (3) Å]. Only one of the amino H atoms participates in hydrogen bonding. The two molecules of the dimer are related by a centre of symmetry and are both planar and parallel to each other. Fig. 1 gives a stereoscopic illustration of the structure.

A discussion of the packing has been given in a previous paper describing the X-ray study (Kvick & Backéus, 1974).

### *The molecular structure*

The molecular dimensions of 2-amino-5-chloropyridine are given in Table 3 and are illustrated in Fig. 2. The only significant differences in bond distances involving non-hydrogen atoms found by neutron and X-ray techniques are present in the distances C(5)-Cl and C(3)-C(4) where the deviations are 7 and 4 e.s.d.'s respectively. The most significant difference in thermal parameters for non-hydrogen atoms also involves the Cl atom where the  $\beta_{33}$  thermal parameter is  $6\sigma$  larger in the X-ray case. The X-N difference syntheses in planes perpendicular to the C(5)-Cl bond show two

large peaks of electron density having their maxima roughly in the plane 1.81 Å away from the C(5) position; the C(5)-Cl nuclear distance is 1.729 (3) Å. It is

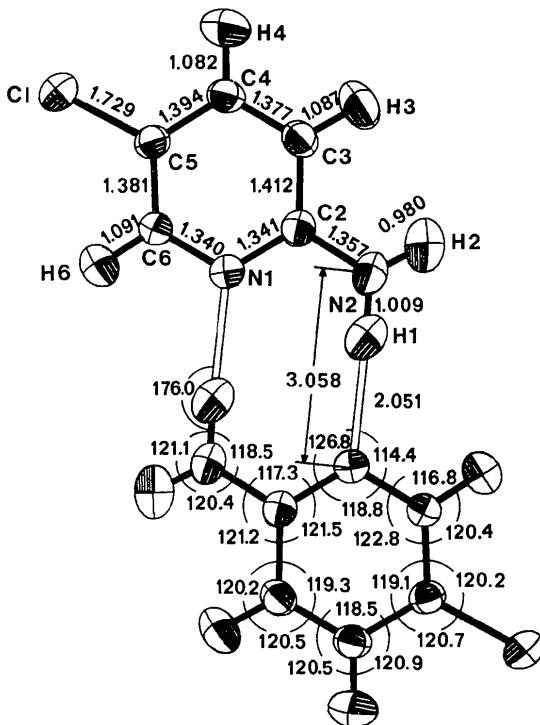

Fig. 2. Bond distances and angles. The values are not corrected for thermal motion.

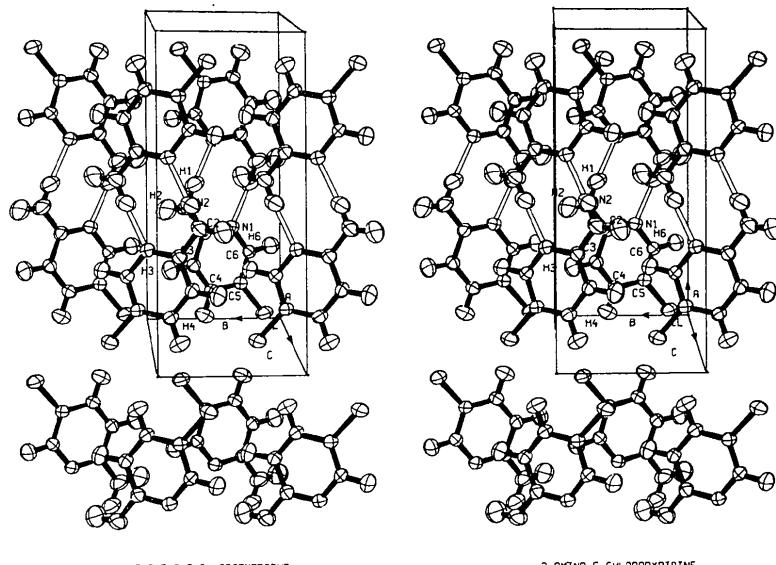

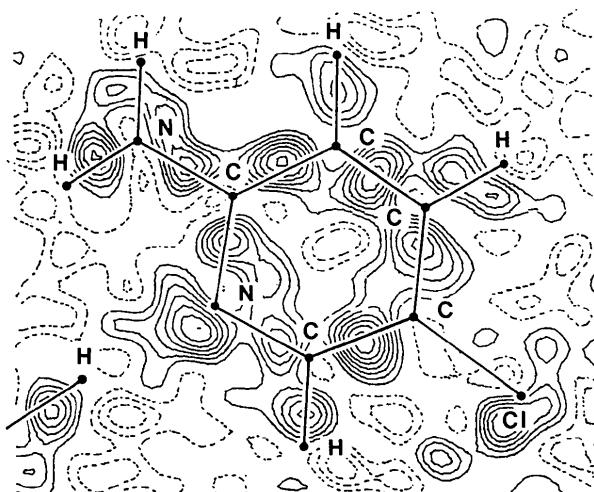

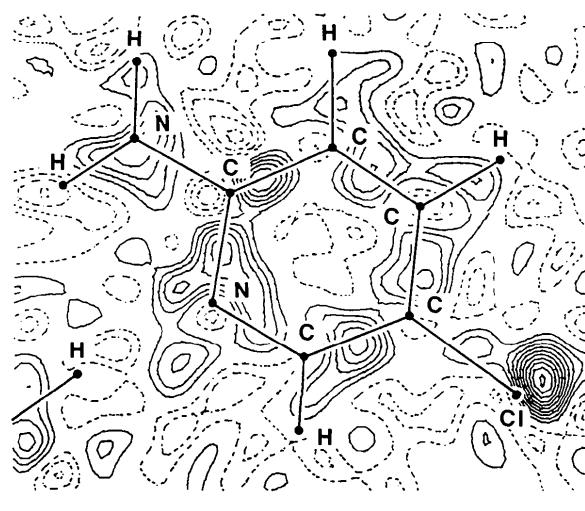

Fig. 1. Stereoscopic illustration of the crystal structure of 2-amino-5-chloropyridine. Covalent bonds are filled and hydrogen bonds are open. The thermal ellipsoids are scaled to enclose 50 % probability.

possible that the difference in the C(5)-Cl distance is associated with a hybridization giving lone-pair electrons in these regions. However, caution must be used in the interpretation of X-N syntheses in the vicinity of atoms heavier than the first row elements. The spherical atomic scattering factors presently used for heavier atoms may well be of a quality which gives rise to artifacts in the vicinity of these atoms.

\* Kvick & Backéus (1974).

The quality of the X-N syntheses in the plane of the pyridine ring appears generally to be excellent. Fig. 3 shows the results found in the plane of the ring and in a plane displaced 0.4 Å from the ring. Electron densities are found in the covalent bonds and at the expected lone-pair regions. Of particular interest is the difference of hybridization of the N atoms. The pyridine N atom is expected to have an electron lone-pair in the plane of the ring whereas the amino N atom is expected to have an electron lone-pair perpendicular to the ring. This expectation is convincingly verified in Fig. 3. The X-N syntheses also explain the well-known disparity in bond distances involving covalently attached H atoms determined by X-ray and neutron diffraction techniques. The asphericity of the electron distribution around H atoms results in apparently shorter X-H distances found by X-ray studies. The difference in H atomic positions is close to 0.13 Å in C-H bonds. In N-H and O-H bonds the difference varies considerably with the hybridization and hydrogen-bond involvement of the N-H and O-H groups. A more extensive discussion of these matters is given by Kvick (1974).

Typical systematic differences in X-H bond distances determined by X-ray and neutron diffraction are given in Table 4, which summarizes three comparative neutron and X-ray studies. Similar disparities are also found by Coppens (1974), Lundgren & Tellgren (1974), Hanson, Sieker & Jensen (1972), and Thomas (1975). The systematic difference is only present in the bond distances; the bond angles are not affected in X-H

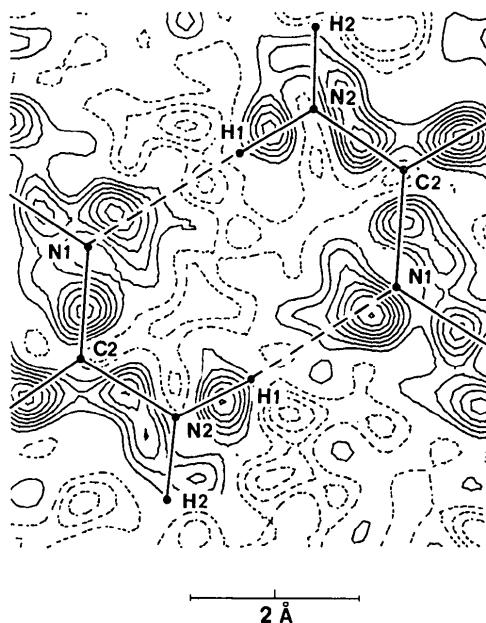

Fig. 4. X-N difference synthesis in the plane of the hydrogen bond. The contours are drawn at  $0.06 \text{ e } \text{\AA}^{-3}$  intervals; negative regions are represented by dashed lines.

bonds (Table 4). A similar but smaller effect exists for first row elements in a pronounced asymmetric bonding environment (Coppens, 1974).

#### The hydrogen bond

The 2-amino-5-chloropyridine molecules are linked to produce cyclic dimers via pairs of N-H $\cdots$ N hydrogen bonds across centres of symmetry. The N $\cdots$ N bond distance is 3.058 (3) Å; the H $\cdots$ N separation is 2.051 (3) Å and the bond is nearly linear with an N-H $\cdots$ N angle of 174°. An X-N synthesis in the plane of the bond is presented in Fig. 4. It is clearly seen that the positive side of H(1) points toward the electron lone-pair region of the pyridine N(1). The second H atom H(2) of the amino group is not involved in hydrogen bonding. The N(2)-H(2) bond distance of 0.980 (3) Å gives an indication of the bond distance for an N-H bond not involved in hydrogen bonding in

Table 6 (*cont.*)

value in our case may be attributed partly to the charge redistribution in the amino group upon hydrogen-bond formation with the N(2)-H(1) group as the donor. The X-N synthesis in Fig. 4 shows a markedly larger electron density in the N(2)-H(1) bond than in the N(2)-H(2) bond in agreement with MO calculations on a dimer of formamide by Dreyfus, Maigret & Pullman (1970).

The thermal motion parameters  $\beta_{ij}$  were converted to thermal vibration tensor elements  $U_{ij}$ , referred to an orthogonal Cartesian axial system parallel to **a**, **b**, and **c**\*. The tensor elements of the Cl atom and the heavy atoms in the pyridine ring were fitted to rigid-body motions expressed in terms of **T**, **L** and **S** tensors (Schomaker & Trueblood, 1968). The r.m.s. deviation of the experimental  $U_{ij}$  values from those calculated from the values of **T**, **L** and **S** is 0.004 Å<sup>2</sup>. The r.m.s. amplitudes of translation along the principal axes are 0.18, 0.17 and 0.17 Å. The principal librational axes have r.m.s. amplitudes of 5.3, 3.9 and 2.7°, while the effective screw translations are all 0.018 Å or less. Corrections to bond lengths between atoms in the rigid body were obtained from the rigid-body librations and corrected distances are included in Table 3. The root-mean-square components  $R_i(\text{\AA})$  of thermal displacement of the atoms along their ellipsoid principal axes are given in Table 5.

The authors wish to express their gratitude to Professor I. Olovsson for his active interest in this work and to Mr H. Karlsson for valuable assistance in growing the crystals.
