We wish to record our thanks to Dr Martin-Lomas and Dr Chacon-Fuertes, CSIC (Madrid), for the crystals. We also thank the Centro de Proceso de Datos del Ministerio de Educación y Ciencia (Madrid) for allowing us to use the 1108 UNIVAC computer. All calculations were performed with the X-RAY System of Crystallographic Programs.

#### Abstract

Triclinic, $P \overline{1}, a=9.835$ (3), $b=11.068$ (3), $c=9.006$ (2) $\AA, \quad \alpha=92.04$ (2), $\quad \beta=119.28$ (2), $\gamma=$ $96.36(2)^{\circ}, V=845 \cdot 4 \AA^{3}, Z=2, D_{c}=2.21 \mathrm{~g} \mathrm{~cm}^{-3}, D_{m}=$ $2.17 \mathrm{~g} \mathrm{~cm}^{-3}$ (by flotation in an iodomethane-chloroform mixture). Mo $K \alpha_{1}$ radiation, $\lambda=0.70926 \AA$, $\mu($ Mo $K \alpha)=30 \cdot 1 \mathrm{~cm}^{-1}, T=21(1)^{\circ} \mathrm{C}$, final $R=0.086$ for 2192 observed reflexions. An irregular capped octahedral geometry exists about Mo; Sn (which occupies the capped position) has an irregular trigonal bipyramidal arrangement. One Cl atom is |bonded to both Mo and Sn with bond lengths $2.535^{\circ}(5)$ and $2 \cdot 781$ (4) $\AA$ respectively. The Sn -Mo distance is 2.688 (2) $\AA$.

Introduction. Small red air-stable crystals of the title compound were obtained by crystallization from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. Weissenberg and precession photographs of

one of these crystals (mounted about a and a* respectively) indicated triclinic Laue symmetry. Cell dimensions were obtained from 12 strong reflexions $\left(2 \theta>24^{\circ}\right)$ centred on the Mo $K \alpha_{1}$ peak ( $\lambda=0 \cdot 70926 \AA$ ) without the use of a monochromator. Intensities were collected in two shells $0^{\circ}<2 \theta<30^{\circ}$ and $30^{\circ}<2 \theta<50^{\circ}$ with a $\theta$, $2 \theta$ scan and monochromatized $K \alpha_{1}$ radiation. Otherwise the data were collected as reported by Einstein \& Jones (1972). The variation of standard reflexions was approximately $\pm 5 \%$.
The data set consisted of 3000 unique reflexions of which 2192 were classed as observed $\{I>2 \cdot 35 \sigma(I)$, $\sigma(I)=\left[(T)+(\mathrm{ts} / \mathrm{tb})^{2}\left(B_{1}+B_{2}\right)+(K I)^{2}\right]^{1 / 2}$ where $\mathrm{T}=$ total count, $\mathrm{ts}=$ scan time, $\mathrm{tb}=$ total background count time, $B_{1}$ and $B_{2}$ are the background counts, $K$ is a constant equal to 0.03 , and $I$ is the net count $\}$. The intensities
were corrected for the monochromator polarization and for Lorentz polarization effects, but not for absorption. The last could introduce an extreme error of $\pm 5 \%$ in $F$. The structure was solved by Patterson and Fourier methods.

Full-matrix least-squares refinement of data $(2 \theta<$ $30^{\circ}$ ) gave an $R$ of $0.069\left(R=\Sigma| | F_{o}\left|-\left|F_{c}\right|\right| / \Sigma\left|F_{o}\right|\right)$. At this stage anisotropic temperature factors were needed to describe the $\mathrm{Sn}, \mathrm{Mo}$, and Cl atoms. After this most H atoms were located from a difference synthesis, but where peaks were not found their positions were

(The thermal ellipsoids shown represent a probability of $50 \%$ electron density.)
generated. H atomic parameters were not refined. Following this all the data were employed for full-matrix least-squares refinement which gave a final $R$ of 0.086 . Weights determined from counter statistics $\left(1 / \sigma_{F}\right)^{2}$ were used.
Programs used were those described by Einstein \& Jones (1972). Scattering factors were from Cromer \& Waber (1965) except for H which was from Stewart, Davidson \& Simpson (1965). Sn and Mo were corrected for anomalous dispersion with values listed in International Tables for X-ray Crystallography (1962).
Atomic coordinates and thermal motion parameters are listed in Table 1, interatomic distances and angles in Table 2. Fig. 1 shows the labelling of the atoms.*

Discussion. The compound DTH $\mathrm{Mo}(\mathrm{CO})_{3}\left(\mathrm{SnCl}_{3}\right) \mathrm{Cl}$ (I) (DTH $=2,5$-dithiahexane) was chosen for study as one of a series of organometallic compounds containing metal-metal bonds. In all these compounds sevencoordinate Mo or W has been found with a capped octahedral environment about the central metal atom. For (I) the $\mathrm{Mo}-\mathrm{Sn}, \mathrm{Mo}-\mathrm{Cl}$ and $\mathrm{Sn}-\mathrm{Cl}$ lengths are all considerably shorter than those reported for $\operatorname{bipy}(\mathrm{CO})_{3} \mathrm{ClMoSnCH}_{3} \mathrm{Cl}_{2}$ (II) (bipy $=2,2^{\prime}$-bipyridyl) (Elder \& Hall, 1968).

In (I) and (II) an irregular capped octahedral geometry exists about Mo , with the $-\mathrm{SnCl}_{3}$ or $-\mathrm{SnCl}_{2} \mathrm{CH}_{3}$ group in the unique capping position. Coordination of Sn is irregular trigonal bipyramidal and $\mathrm{Cl}(4)$ is bonded to both Sn and Mo, leading to the 'trigonal' axis being offset as was found in (II). The environment of Sn is quite asymmetric and Mössbauer studies showed very
low values for the isomer shift and quadrupole splitting (Cullen, Pomeroy, Sams \& Tsin, 1976).

In addition an approximate non-crystallographic mirror plane extends through $\mathrm{Mo}, \mathrm{Sn}, \mathrm{Cl}(1)$ and $\mathrm{Cl}(4)$.

To explain the shortened $\mathrm{Sn}-\mathrm{Mo}$ and $\mathrm{Sn}-\mathrm{Cl}$ lengths of (I) relative to (II), we may use Bent's rule, that is, more electropositive substituents prefer hybrid orbitals having more $s$ character. (I) has only one electropositive group (Mo) whereas (II) has two (Mo and $\mathrm{CH}_{3}$ ). One can visualize that in (II), both Mo and $\mathrm{CH}_{3}$ compete for $s$ character whereas in (I) only Mo has preference for $s$ electrons. Then the $\mathrm{Sn}-\mathrm{Cl}$ bonds of (II) can be expected to have more $p$ character than in (I), and so it follows that in (II) they are longer. The Sn-Mo bond in (II) also has more $p$ character than in (I) and so is longer in (II).

Increased competition for $d \pi$ electron density on the transition metal atom in (II) vs (I) due to the bipy group (compared to the DTH group) may also shorten the $\mathrm{Sn}-\mathrm{Mo}$ bond in (II). However, since the electronegativities of $S$ and $N$ in these species are not very different, this effect is probably unimportant. Furthermore, in (I) the better $\pi$ acceptor properties of the $-\mathrm{SnCl}_{3}$ group compared to $-\mathrm{SnCl}_{2} \mathrm{C}_{3} \mathrm{H}_{3}$ in (II) may contribute to the short Mo-Sn length in (I).

In the DTH ligand the $S(1) \cdots S(2)$ bite is 3.306 compared with an $S \cdots S$ bite of $3 \cdot 10 \AA$ reported by Eisenberg (1970). The increased S...S distance would allow an angle nearer $90^{\circ}$ to be subtended in keeping with the octahedral geometry. The covalent radii of Mo and S are 1.61 (Wilson \& Shoemaker, 1957) and $1.04 \AA$ (Pauling, 1960) respectively. This S-Mo length of $2.65 \AA$ can be compared with the observed values of 2.533 (4) and 2.547 (4) $\AA$ indicating the possibility of some $\pi$ character in these bonds.

We thank Dr W. R. Cullen for his gift of the crystals and for his interest in this work. We also acknowledge the support of the National Research Council of Canada.
