# The Crystal Structure of Guanidinium Oxalate Dihydrate Monoperhydrate 

By J. M. Adams and R. G. Pritchard<br>Edward Davies Chemical Laboratories, University College of Wales, Aberystwyth, SY23 1NE, Wales

(Received 5 February 1976; accepted 8 March 1976)

#### Abstract

The structure of $\left[\mathrm{C}\left(\mathrm{NH}_{2}\right)_{3}\right]_{2}(\mathrm{COO})_{2} .2 \mathrm{H}_{2} \mathrm{O} . \mathrm{H}_{2} \mathrm{O}_{2}$ has been determined from microdensitometer-measured intensities and refined to a final $R$ of 0.061 . The geometrical parameters of the ions and molecules are normal with the oxalate ions and $\mathrm{H}_{2} \mathrm{O}_{2}$ molecules disposed across centres of symmetry; both these species are planar. Although the perhydrates of all the alkali metal (and ammonium) oxalates have hydrogen-bonded chains of $\left(\cdots \text { oxalate } \cdots \mathrm{H}_{2} \mathrm{O}_{2} \cdots\right)_{n}$, these are not a feature of the title compound which has a three-dimensional hydrogen-bonding scheme involving eight of the nine H atoms. This compound is much more stable than other oxalate perhydrates.

## Introduction

Perhydrates, i.e. substances containing $\mathrm{H}_{2} \mathrm{O}_{2}$ of crystallization, have been grown from a few organic compounds, notably urea (Lu, Hughes \& Giguère, 1941) and alkali metal oxalates (Pedersen, 1969). However, these have not been very stable and, in general, undergo decomposition at room temperature over a period of days. The structures of the oxalate hydrates and perhydrates have been shown by Pedersen (1969) to consist of chains (Fig. 1) which are linked in the ammonium salt by hydrogen bonds. We have taken this opportunity to maximize the number of possible hydrogen bonds by using the guanidinium ion $\left[\mathrm{C}\left(\mathrm{NH}_{2}\right)_{3}\right]^{+}$as a method of increasing the stability of the perhydrate. The relative stabilities of ammonium oxalate perhydrate and the title compound are indicated by the time taken for a $20 \%$ fall in 'activity', approximately 50 h for the former and 250 h for the latter.

## Experimental

Guànidinium oxalate was prepared by reaction of guanidinium carbonate with the acid; the salt was recrystallized at room temperature from $30 \%(\mathrm{w} / \mathrm{v})$ hydrogen peroxide. Analysis of the crystals for $\mathrm{H}_{2} \mathrm{O}_{2}$ was carried out by $\mathrm{I}_{2} / \mathrm{S}_{2} \mathrm{O}_{3}^{2-}$ titrations and the stability studies were at room temperature and humidity (approximately $50 \%$ ). Two different crystals (both about $0.7 \times 0.7 \times 0.7 \mathrm{~mm}$ ) were used to collect the two data sets ( $h k 0-h k 3, h 0 l-h 3 l$ ) on a Stoe-Weissenberg camera. The crystal data are given in Table 1. The intensities were measured by the SRC Microdensitometer Service at the Atlas Computer Laboratory with an Optronics P1000 scanner.

Table 1. Crystal data

[^0]
## Determination of the structure

Intensities were measured for 1333 reflexions, of which 585 were unique. The planes which were too weak to be measured by the scanner were given intensities equal to half the weakest observed value on the appropriate film pack, and the data were corrected for Lorentz and polarization effects. A Wilson plot gave the low $B$ of $1.0 \AA^{2}$, and $E$ values were generated.

The structure was solved with MULTAN (Germain, Main \& Woolfson, 1970) with the 119 planes with $E>1 \cdot 4$. An $E$ map computed with the phases from the set with the highest figure of merit $(1-20)$ revealed a chemically reasonable set of peaks.
Refinement was by anisotropic full-matrix least squares; the H atoms were found from a difference synthesis when $R$ was $0 \cdot 08$. During further refinement the thermal parameters of the H atoms were constrained to be equal to the mean value of ( $U_{11}+U_{22}+$ $U_{33}$ ) for the heavy atoms. In the last cycle the shifts were of the order of the appropriate standard deviations; the final $R$ was 0.061 . The scattering factors were those listed in International Tables for X-ray Crystallography (1962) and all calculations, except the structure solution, were made with the X-RAY system (1972).

Final atomic and thermal parameters are given in Tables 2 and 3.*

## Description and discussion of the structure

Bond lengths and angles (Table 4) in the oxalate ion are similar to those previously found (Pedersen, 1969) although the $\mathrm{C}-\mathrm{C}$ bond is closer to the theoretical single-bond length of $1.54 \AA$ than to the lengthened value sometimes observed (Hodgson \& Ibers, 1969) of up to $1.57 \AA$. The guanidinium ion parameters are likewise close to those usually found with all the C-N bonds of equal length (Adams \& Small, 1976), thus contrasting with guanidinium carbonate where one of

| $\mathrm{O}(1)-\mathbf{H}(1)$ | $1 \cdot 18$ (9) | $\mathrm{H}(2)-\mathrm{O}(3)-\mathrm{H}(1)$ | 115 (7) |
| $\mathrm{O}(1)-\mathrm{H}(2)$ | 0.74 (9) | $\mathrm{H}(8)-\mathrm{N}(1)-\mathrm{C}(2)$ | 125 (6) |
| $\mathrm{O}(4)-\mathrm{H}(3)$ | 1.03 (7) | $\mathrm{H}(8)-\mathrm{N}(1)-\mathrm{H}(9)$ | 121 (7) |
| $\mathrm{N}(1)-\mathrm{H}(8)$ | 0.87 (8) | $\mathrm{H}(9)-\mathrm{N}(1)-\mathrm{C}(2)$ | 113 (4) |
| $\mathrm{N}(1)-\mathrm{H}(9)$ | $0 \cdot 98$ (9) | $\mathrm{H}(6)-\mathrm{N}(2)-\mathrm{C}(2)$ | 113 (6) |
| $\mathrm{N}(2)-\mathrm{H}(6)$ | $0 \cdot 85$ (7) | $\mathrm{H}(6)-\mathrm{N}(2)-\mathrm{H}(7)$ | 130 (8) |
| $\mathrm{N}(2)-\mathrm{H}(7)$ | $0 \cdot 90$ (8) | $\mathrm{H}(7)-\mathrm{N}(2)-\mathrm{C}(2)$ | 117 (5) |
| $\mathrm{N}(3)-\mathrm{H}(4)$ | 0.72 (9) | $\mathrm{H}(4)-\mathrm{N}(3)-\mathrm{C}(2)$ | 117 (6) |
| $\mathrm{N}(3)-\mathrm{H}(5)$ | 0.94 (7) | $\mathrm{H}(4)-\mathrm{N}(3)-\mathrm{H}(5)$ | 131 (8) |
|  |  | $\mathrm{H}(5)-\mathrm{N}(3)-\mathrm{C}(2)$ | 112 (5) |

these bonds is significantly longer than the other two (Adams \& Small, 1974).

The $\mathrm{O}-\mathrm{O}$ distance in the $\mathrm{H}_{2} \mathrm{O}_{2}$ molecule is similar to those in other perhydrates and peroxo compounds (Pedersen, 1972) and the HOO angle is close to that found by Busing \& Levy (1965) in solid $\mathrm{H}_{2} \mathrm{O}_{2}\left(102 \cdot 7^{\circ}\right)$ although the e.s.d. is very large. The dihedral angle between the two $\mathrm{H}-\mathrm{O}$ bonds is $180^{\circ}$ since the molecule is planar (Table 5); dihedral angles between 90 and $180^{\circ}$ have been found in other perhydrates, the value apparently being very sensitive to the environment of the $\mathrm{H}_{2} \mathrm{O}_{2}$ molecules.

$$

There is a major difference between the title compound and all other oxalate perhydrates in that none has previously been reported which contains water together with the hydrogen peroxide of crystallization. The hydrogen-bonding scheme is the same in all these other perhydrates; there are infinite chains of type $\left(\cdots \text { oxalate } \cdots \mathrm{H}_{2} \mathrm{O}_{2} \cdots\right)_{n}$ with the cations situated between them, whereas this structural feature is not present in the guanidinium salt where there is a complicated three-dimensional hydrogen-bonding network (Figs. 2 and 3, Table 6).

Table 6. Hydrogen-bonding geometry

| Bonds | Distances ( $\AA$ ) |  | $\underset{a b c}{\text { Angles }\left({ }^{\circ}\right)}$ |
| :---: | :---: | :---: | :---: |
| $(a-b \cdots c)$ | bc | $a c$ |  |
| $\mathrm{O}(4)-\mathrm{H}(3) \cdots \mathrm{O}\left(1^{\text {i }}\right.$ ) | 1.66 (7) | $2 \cdot 67$ (1) | 163 (7) |
| $\mathrm{O}(1)-\mathrm{H}(1) \cdots \mathrm{O}(2)$ | $1 \cdot 85$ (7) | $2 \cdot 90$ (1) | 146 (7) |
| $\mathrm{O}(1)-\mathrm{H}(2) \cdots \mathrm{O}\left(3^{\text {II }}\right.$ ) | $2 \cdot 04$ (8) | 2.75 (1) | 159 (8) |
| $\mathrm{N}(1)-\mathrm{H}(8) \cdots \mathrm{O}\left({ }^{\text {iil }}\right.$ ) | 1.97 (8) | $2 \cdot 84$ (1) | 174 (7) |
| $\mathrm{N}(1)-\mathrm{H}(9) \cdots \mathrm{O}\left(2^{\text {iv }}\right.$ ) | 2.07 (8) | $2 \cdot 84$ (1) | 134 (6) |
| $\mathrm{N}(2)-\mathrm{H}(6) \cdots \mathrm{O}\left(4^{\text {V }}\right.$ ) | 2.25 (9) | $3 \cdot 02$ (1) | 149 (9) |
| $\mathrm{N}(2)-\mathrm{H}(7) \cdots \mathrm{O}(2)$ | 1.92 (9) | $2 \cdot 81$ (1) | 168 (6) |
| $\mathrm{N}(3)-\mathrm{H}(4) \cdots \mathrm{O}\left(1^{\text {v1 }}\right.$ ) | $2 \cdot 20$ (9) | $2 \cdot 91$ (1) | 172 (11) |
| Equivalent positions |  |  |  |
| (i) $1+x \quad y$ | (ii) | $1-x$ | $-\frac{1}{2}+y \quad \frac{1}{2}-z$ |
| (iii) $-x \quad 1-y \quad 1-z$ | (iv) | $-1+x$ | $\frac{1}{2}-y \quad \frac{1}{2}+z$ |
| (v) $x^{\frac{1}{2}-y} \frac{1}{2}+z$ | (vi) | $1-x$ | $1-y-z$ |

The peroxide $\mathrm{O}(4)$ forms a hydrogen bond ( $2 \cdot 69 \AA$ ) to the water $\mathrm{O}(1)$, which also accepts a hydrogen bond ( $2.92 \AA$ ) from one of the guanidinium groups. The water molecule donates two hydrogen bonds ( 2.75 and $2.91 \AA$ ) to different oxalate anions. The guanidinium ion also provides a hydrogen bond ( 3.01 $\AA$ ) to the peroxide O and three other hydrogen bonds ( $2 \cdot 81,2.83$ and $2.85 \AA$ ) to oxalate ions. This hydrogenbonding scheme uses eight of the nine possible H atoms.

We thank Professor J. M. Thomas for his advice and encouragement, and the Science Research Council for the award of a Research Studentship to one of us (R.G.P.).

# Structure Cristalline du Polyphosphate de Lithium-Ammonium, $\mathbf{L i}_{\mathbf{2}} \mathbf{N H}_{\mathbf{4}}\left(\mathbf{P O}_{3}\right)_{3}$ 

Par M. T. Averbuch-Pouchot, A. Durif et J. C. Guitel<br>Laboratoire des Rayons X, CNRS, B.P. 166, Centre de Tri 38042, Grenoble Cédex, France

(Reçu le 12 mars 1976, accepté le 19 mars 1976)
Lithium ammonium polyphosphate, $\mathrm{Li}_{2} \mathrm{NH}_{4}\left(\mathrm{PO}_{3}\right)_{3}$, is orthorhombic, $P b c a$, with a unit cell $a=12 \cdot 199(5)$, $b=13.047$ (5),$c=10.537$ (5) $\AA$ and $Z=8$. The crystal structure of this salt has been solved by using 2297 independent reflexions. The final $R$ value is $0.043 . \mathrm{PO}_{3}$ chains, with a period of six tetrahedra, run along the $b$ direction. Associated cations, all in fourfold coordination, also form chains running along the $b$ direction.

## Introduction

Les cristaux du polyphosphate de lithium-ammonium, $\mathrm{Li}_{2} \mathrm{NH}_{4}\left(\mathrm{PO}_{3}\right)_{3}$, se présentent sous la forme de plaquet-
tes épaisses à contours irréguliers. On les prépare facilement en calcinant à $350^{\circ} \mathrm{C}$, durant une quinzaine d'heures, un mélange de 3 g de carbonate de lithium et de 20 g de phosphate biammonique. Les cristaux
