Barnes, 1960), although those observed here seem particularly marked. They are most probably due to intermolecular interactions; it may be significant that proflavine, like the hemisulphate, contrasts with most
other aminoacridine crystal structures in not being highly stacked.

The crystal structure (Fig. 3) is shown in c projection. The molecules are held together by a network of hydrogen bonds between the proflavine N atoms and $\mathrm{H}_{2} \mathrm{O}$ molecules, which are situated on crystallographic mirrors. $\mathrm{N}(2)-\mathrm{O}(10)$ is $2.703 \AA$, with the $\mathrm{H}_{2} \mathrm{O}$ acting as donor. Each $\mathrm{H}_{2} \mathrm{O}$ is also hydrogen bonded ( $3.008 \AA$ ) to two symmetry-related $\mathrm{N}(9)$ atoms in adjacent molecules. The proflavine bases are notably unstacked in the lattice, with only minimal overlap between a molecule and its $C$-centred mate.

We are grateful to the Cancer Research Campaign and the Lawson Tait Trust for support.

#### Abstract

In}_{2} \mathrm{Te}_{5}, M=867 \cdot 64\), monoclinic, $C c ; a=4 \cdot 39$ (1), $b=16 \cdot 39$ (1), $c=13.52$ (1) $\AA, \beta=91 \cdot 65$ (5) ${ }^{\circ}, D_{m}=$ $5.95, D_{c}=5.94 \mathrm{~g} \mathrm{~cm}^{-3} ; U=969 \cdot 5 \AA^{3}, Z=4, F(000)=$ 1432. The structure was solved from Patterson syntheses with Mo $K \alpha$ X-ray data and refined by blockdiagonal least squares to $R=8 \%$ for 1223 structure factors. The material is composed of two sheets of atoms running perpendicular to $\mathbf{c}^{*}$. These are constructed of chains of four-membered $\mathrm{In}-\mathrm{Te}$ rings; each In is tetrahedrally coordinated indicating that it may be thought of as being $s p^{3}$ hybridized with an average In-Te bond of $2 \cdot 832$ (6) $\AA$, alternating with, and crosslinked by, groups of three Te atoms which on an ionic description are $\left(\mathrm{Te}_{3}\right)^{2-}$ polyanions. The average $\mathrm{Te}-\mathrm{Te}$ bond in this anion is $2.837 \AA$ with an included angle of $100 \cdot 1$ (2) ${ }^{\circ}$.

Introduction. Cell parameters for a phase, $\mathrm{In}_{2} \mathrm{Te}_{5}$, have been quoted (Schubert, Dorre \& Gunzel, 1954; Gerasimov, Abbasov \& Nikolskaya, 1962) and the existence
of a phase with this formula was postulated as a result of a DTA and X-ray investigation of the $\mathrm{In}-\mathrm{Te}$ system (Grochowski, Mason, Schmitt \& Smith, 1964). Following the phase diagram produced by Grochowski et al., an intimate mixture of In and Te in the correct stoichiometric proportions to produce $\mathrm{In}_{2} \mathrm{Te}_{5}$ was placed in a sealed evacuated pyrolysed tube and heated to $550^{\circ} \mathrm{C}$. This temperature was maintained for 24 h whilst the tube was shaken to ensure mixing. The sample was then directionally frozen at $2 \mathrm{~mm} \mathrm{~h}^{-1}$ to $400^{\circ} \mathrm{C}$ and was held there for 48 h before being allowed to cool slowly. This process was repeated with starting compositions to either side of $\mathrm{In}_{2} \mathrm{Te}_{5}$. In all cases the resulting boules were inhomogeneous but did contain regions of shiny black lamellar material from which crystals were extracted which proved to be $\mathrm{In}_{2} \mathrm{Te}_{5}$. The density measured experimentally by toluene immersion was $5.95 \mathrm{~g} \mathrm{~cm}^{-3} .1223$ reflexions, of which 57 were recorded as zero were collected from Weissenberg photographs taken about a with multiple-film packs and Mo $K \alpha$
radiation. Intensities for 908 reflexions were measured with a Joyce-Loebl flying-spot densitometer. Very weak reflexions were measured visually. Data were corrected for Lorentz and polarization factors and, for visual data, for spot elongation on upper layers. No absorption correction was made since the crystal was fairly regular in cross-section with $\mu R<0 \cdot 5$. Overall scale and temperature factors were obtained by Wilson's (1942) method. The structure was solved from minimum functions based on generalized Patterson syntheses. Block-diagonal least-squares refinement of positional, scale and anisotropic thermal parameters resulted in a final $R=0.08$ where $R=\sum| | F_{o}\left|-\left|F_{c}\right|\right| /$ $\Sigma\left|F_{o}\right|$. Scattering factors were from International Tables for X-ray Crystallography (1974). Table 1 gives the atomic coordinates and anisotropic thermal parameters; bond lengths and angles within the two sheets of atoms forming the structure are given in Table 2; other relevant interatomic distances including those between sheets are given in Table 3.*

* A list of structure factors has been deposited with the British Library Lending Division as Supplementary Publication No. SUP 31791 ( 6 pp.). Copies may be obtained through The Executive Secretary, International Union of Crystallography, 13 White Friars, Chester CH1 1NZ, England.

Discussion. Due to their similar scattering powers it is difficult to distinguish the atom types from X-ray data; an analysis of interatomic distances leads to the atom designations and the system of bonding shown in Fig. 1. The material is composed of endless parallel chains of atoms running along a based on four-membered $\mathrm{In}-\mathrm{Te}$ rings $\operatorname{In}(1), \mathrm{Te}(1), \ln (2)$ and $\mathrm{Te}(2)$. These chains alternate with, and are cross-linked by, tightly bound $\mathrm{Te}(3)-\mathrm{Te}(4)-\mathrm{Te}(5)$ groups to form a continuous sheet of atoms perpendicular to $\mathbf{c}^{*}$. The structure contains two such sheets; within each sheet there is a pseudo centre of symmetry midway between $\operatorname{In}(1)$ and $\operatorname{In}(2)$ and a pseudo twofold axis parallel to a through $\mathrm{Te}(4)$. These symmetry operations hold only within their particular sheet of atoms and do not extend to neighbouring sheets.

The existence of systems of tightly bound Te atoms in the structure was expected in that valence saturation could only be achieved by the formation of a Te polyanion. Since the two In atoms are not mutually bonded but occur in environments that are almost identical and which are typical of trivalent In , then on an ionic formulation the compound can only be $2\left(\mathrm{In}^{3+}\right)$ -$\left(\mathrm{Te}_{3}^{2-}\right) 2\left(\mathrm{Te}^{2-}\right)$. This necessitates a triatomic anion which was identified as $\mathrm{Te}(3)-\mathrm{Te}(4)-\mathrm{Te}(5)$. In isolation

Fig. 1. $\mathrm{In}_{2} \mathrm{Te}_{5}$. A projection of the structure down a showing the method of bonding. The atoms are scaled to the respective ionic radii of $\operatorname{In}^{3+}(0.81 \AA)$ and $\mathrm{Te}^{2-}(2 \cdot 22 \AA)$. Shaded and non-shaded atoms lie near $x=\frac{1}{2}$ and 0 respectively.
an analysis of bond lengths leads to an ambiguity in the designation of $\mathrm{Te}(4)$ which arises because the typical In-Te bond distance is $2.85 \AA$, whereas the average bond length in this group is 2.832 (6) $\AA$ with an included angle of $100 \cdot 1(2)^{\circ}$. This bond length, however, is similar to the $\mathrm{Te}-\mathrm{Te}$ bond of 2.70 (1) $\AA$ found in $p, p^{\prime}$-dichlorodiphenylditelluride (Kruse, Marsh \& McCullough, 1957) and to the Te covalent single bond radius ( $2 \cdot 74 \AA$ ), whilst the configuration is similar to that of the $\left(\mathrm{S}_{3}\right)^{2-}$ polyanion in $\mathrm{BaS}_{3}$ (Miller \& King, 1936) which has an included angle of $103^{\circ}$. In elemental hexagonal Te , which contains endless spiral chains of atoms, the average Te-Te bond in the chain is $2.86 \AA$ with a $\mathrm{Te}-\mathrm{Te}-\mathrm{Te}$ bond angle of $102^{\circ}$; the closest distance of approach of the chains is $3 \cdot 47 \AA$ (Wyckoff, 1963). Refinement of the structure with the central atom in the group as In resulted in significantly low thermal parameters for this atom. It was therefore concluded that the central atom in this group was a Te atom, $\mathrm{Te}(4)$; the group thus forms a triatomic anion. In $\mathrm{In}_{2} \mathrm{Te}_{5}$ the $\left(\mathrm{Te}_{3}\right)^{2-}$ anions are arranged in chevron formation in the $x z$ plane and the closest distances of approach between the anions are $\mathrm{Te}(4)-\mathrm{Te}\left(3_{1}\right)=3.355$ (7) and $\mathrm{Te}(4)-\mathrm{Te}\left(5_{1}\right)=3 \cdot 377$ (7) $\AA$.

The environment of $\mathrm{Te}(4)$, the central atom of the $\left(\mathrm{Te}_{3}\right)^{2-}$ anion, indicates that this atom may be thought of as being in a state of $s p^{3}$ hybridization with two lone pair orbitals, the repulsion from which would account for the reduction of the $\mathrm{Te}(3)-\mathrm{Te}(4)-\mathrm{Te}(5)$ bond angle from the ideal tetrahedral value.

Bonds and contacts from $\mathrm{Te}(1)$ and $\mathrm{Te}(2)$ not involving the polyanion suggest that these two atoms have a diameter comparable with that of $\mathrm{Te}^{2-}(4 \cdot 44 \AA$.) In this respect these two atoms are very similar to those existing in $\mathrm{In}_{4} \mathrm{Te}_{3}$. In both structures the short axial length is determined by this diameter. An analysis of the contacts and bonds around $\mathrm{Te}(3)$ and $\mathrm{Te}(5)$ show that these are on average significantly shorter by about $0 \cdot 15 \AA$ than other comparable distances in the structure. The shortest $\mathrm{Te}-\mathrm{Te}$ distances in the structure, with the exception of those around $\mathrm{Te}(4)$, are those of 3.712 (1) $\AA$ between the end atoms of neighbouring ( 3 Te$)^{2-}$ anions in adjacent sheets of atoms, $\mathrm{Te}(3)-$ $\mathrm{Te}\left(5_{4}\right)$. This distance is approximately $0.3 \AA$ less than the usual value indicating a reduction in the radius of the end atoms of $0.15 \AA$. The bonds from $\mathrm{Te}(3)$ and $\mathrm{Te}(5)$ to $\operatorname{In}(2)$ and $\operatorname{In}\left(1_{2}\right)$ are also significantly shorter than other $\mathrm{In}-\mathrm{Te}$ bonds in the structure, averaging 2.73 against $2.86 \AA$. Each In is surrounded by four Te atoms in approximately tetrahedral coordination indicating that on a covalent description they may be thought of as being $s p^{3}$ hybridized. The average $\mathrm{In}-\mathrm{Te}$ bond lengths quoted above compare with that of $2 \cdot 88 \AA$ found in $\mathrm{In}_{3} \mathrm{Te}_{4}$ (Hogg \& Sutherland, 1973).

The authors thank Mr G. Bucknell for the preparation of the samples, Dr P. G. Nelson for advice concerning the bonding, the SRC for the grant to purchase the densitometer and Drs C. Morgan, H. H. Sutherland and M. J. Mottram for the computer programs. One of us (P.D.W.) is indebted to Reckitt and Colman Ltd. for the funding of a research studentship.
