presence of aqueous ammonium phosphate solutions. Particularly, struvite is reported to react with a saturated solution of ammonium dihydrogen phosphate to form hannayite, which is then slowly replaced by schertelite; these reactions can be summarized as follows:

$$
\begin{aligned}
& 3 \text { struvite }+3 \mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{4} \rightleftarrows \\
& \text { hannayite }+2\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{4}+10 \mathrm{H}_{2} \mathrm{O} \rightleftarrows \\
& 3 \text { schertelite }+6 \mathrm{H}_{2} \mathrm{O} \text {. }
\end{aligned}
$$

Inversely, schertelite and hannayite undergo hydrolytic reactions dissolving incongruently in water:

$$
\begin{aligned}
& \text { schertelite }+2 \mathrm{H}_{2} \mathrm{O} \underset{ }{\rightleftarrows} \\
& \text { struvite }+\mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{4} \text {, hannayite }+4 \mathrm{H}_{2} \mathrm{O} \rightleftarrows \\
& \text { struvite }+2 \text { newberyite }+\mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{4} .
\end{aligned}
$$

Such transformations also probably occur in human renal liquids under pathological conditions. They can be explained by the strong tendency of systems with this chemical composition to give crystals characterized by a layered structure, where the amount of $\mathrm{NH}_{4}^{+}$ions between layers and the degree of condensation of coordination polyhedra inside the layers vary according to the concentrations of the different chemical species. When hannayite transforms into schertelite, for instance, the condensation of polyhedra decreases strongly, with the formation of isolated
$\mathrm{Mg}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\left(\mathrm{OPO}_{2} \mathrm{OH}\right)_{2}$ groups. The first bonds which break in hannayite are likely to be $\mathrm{Mg}(2)-\mathrm{O}(3)$ and $\mathrm{Mg}(2)-\mathrm{O}(7)$ (Fig. 2), since they involve the most underbonded O atoms in the structure ( $\sum s_{i}=1.83$ v.u.) ; this should be true both for complete solubilization of crystals and for incomplete solubilization with partial solid-state reaction. The latter mechanism would agree with the fact that, by breaking $\mathrm{Mg}(2)-\mathrm{O}(3)$, isolated
groups of $\mathrm{Mg}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\left(\mathrm{OPO}_{2} \mathrm{OH}\right)_{2}$ are formed, which could build up the schertelite crystal framework.

The X-ray intensities were measured at the Centro di Studio del C.N.R. per la Cristallografia Strutturale, Pavia.

Research was supported by the Consiglio Nazionale delle Ricerche, Roma.

# Crystallographic Studies of Bis-( $\boldsymbol{N}$-p-tolylsalicylaldiminato)copper(II) 

By J. M. Bindlish, S. C. Bhatia and Prem C. Jain<br>Department of Chemistry, Kurukshetra University, Kurukshetra, India

(Received 1 March 1976; accepted 24 April 1976)

#### Abstract

The structure of bis-( $N$ - $p$-tolylsalicylaldiminato)copper(II) has been determined by the photographic method and refined to $R=0.09$. The crystals are monoclinic needles, $a=13 \cdot 584, b=7 \cdot 546, c=12 \cdot 221$ $\AA, \beta=110 \cdot 8^{\circ}, Z=2$. The structure consists of discrete molecules in which the metal atom exhibits trans-planar fourfold coordination and has $\mathrm{Cu}-\mathrm{O} 1.899$ and $\mathrm{Cu}-\mathrm{N} 2.010 \AA$. The p-tolyl group is inclined by $124^{\circ}$ to the salicylaldimine plane.

## Introduction

In order to gather more information on the structural features and their dependence on various steric and
electronic effects in the presence of different types of substituents on the N of the salicylaldimine (designated hereafter sim) moiety, considerable attention has been given to the study of solid-state properties. Holm,

Everett \& Chakravorty (1966) have reported (p-tolyl$\operatorname{sim})_{2} \mathrm{Cu}$ to be diamagnetic in the solid state. We have now determined its crystal structure by X-ray diffraction. A preliminary account of the crystal data has appeared (Bhatia, Bindlish \& Jain, 1975).

## Experimental

The sample was prepared by the method of Holm, Everett \& Chakravorty (1966). Oscillation and Weissenberg photographs showed the crystals to be monoclinic.

## Crystal data

$\mathrm{C}_{28} \mathrm{H}_{24} \mathrm{~N}_{2} \mathrm{O}_{2} \mathrm{Cu}, \quad M=483 \cdot 5 ; \quad a=13.584 \quad$ (7), $\quad b=$ 7.546 (10),$c=12.221$ (9) $\AA, \beta=110.8$ ( 8$)^{\circ}, \quad U=1170$ $\AA^{3}$; space group $P 2_{1} / a ; D_{c}=1 \cdot 37, D_{m}=1.41 \mathrm{~g} \mathrm{~cm}^{-3}$ for $Z=2 ; \mu(\mathrm{Cu} K \alpha)=15.90 \mathrm{~cm}^{-1}, \lambda=1.5418 \AA$.

A crystal, $0.50 \times 0.35 \times 0.10 \mathrm{~mm}$, was mounted along b (needle direction). Integrated intensities for the $h 0 l \rightarrow h 4 l$ layers were collected by the equi-inclination Weissenberg method with a four-film pack and an exposure of 80 h for each layer. Intensities for the $0 k l \rightarrow 2 k l$ layers were also collected with another crystal of nearly the same size. The estimation of intensity was carried out by the visual method with a calibrated strip. Out of 1165 independent reflexions 94 were termed unobserved. Each reflexion was corrected for Lorentz and polarization effects, but not for absorption. In the final stages of refinement secondary extinction corrections were applied.

## Structure solution and refinement

With $Z=2, \mathrm{Cu}$ should occupy the special positions 000 and $\frac{1}{2} \frac{1}{2} 0$. Initial structure factor calculations with Cu gave $R=0 \cdot 51$. A series of Fourier syntheses led to the location of all non-hydrogen atoms. Further refinement of the positional and isotropic thermal parameters reduced $R$ to $0 \cdot 13$. Least-squares refinement with an-
isotropic temperature factors gave $R=0 \cdot 105$. A difference map at this stage revealed the positions of all H atoms. The observed positions were in good agreement with those calculated. The positions of the H atoms and their isotropic temperature factor ( $B=4.0 \quad \AA^{2}$ ) were not refined but were included in the subsequent refinement.

Finally, refinement was carried out with weights $V w=1 /\left(1.62-0.027 F_{o}\right)$ for $F_{o} \leq 15.5, \quad V w=1 /(0.64+$ $0.037 F_{o}$ ) for $F_{o}>15.5$; giving $R=0.09$. Scattering factors were taken from International Tables for $X$-ray Crystallography (1962).

All calculations were performed on CDC 3600 and ICL 1905E computers. Programs employed included the Fourier summation program of Blount (1965), the least-squares program of Busing, Martin \& Levy (1962), the NRC programs of Ahmed, Hall, Pippy \& Huber (1970), the CALCAT program for hydrogen of Watenpaugh (1972) and ORTEP (Johnson, 1970).

## Discussion

The molecules lie practically in the $x z$ plane. Cu has a trans-planar configuration. The benzene ring of the salicylaldimine group has a mean bond length of $1 \cdot 40 \AA$ and an interbond angle of $120^{\circ}$, whilst in the $p$-tolyl group it has mean values of $1.39 \AA$ and $119.9^{\circ}$. C(11)$\mathrm{C}(14), 1.54 \AA$, is normal taking into account the high anisotropy for $\mathrm{C}(14) . \mathrm{C}(6)-\mathrm{C}(7)-\mathrm{N}, 128^{\circ}$, seems to be a little large (Table 4) but agrees well with the values

Fig. 1. Bis-( $N$ - $p$-tolylsalicylaldiminato)copper(II) projected on to the [100] plane.

found in (ethylsim) ${ }_{2} \mathrm{Cu}$ (Clark, Hall \& Waters, 1969) and (isopropylsim) ${ }_{2} \mathrm{Cu}$ (Orioli \& Sacconi, 1966). $\mathrm{Cu}-\mathrm{N}$, $2 \cdot 01$, and $\mathrm{Cu}-\mathrm{O}, 1 \cdot 90 \AA$, fall within the range reported for 21 sim-Cu molecules (Jain \& Syal, 1973). Although there is a slight increase in both the $\mathrm{Cu}-\mathrm{O}$ and $\mathrm{Cu}-\mathrm{N}$ lengths compared to (phenylsim) ${ }_{2} \mathrm{Cu}$ (Wei, Stogsdill \& Lingafelter, 1964), the difference of $0 \cdot 11 \AA$ is in excellent agreement. The $\mathrm{CH}_{3}$ group of the $p$-tolyl group is quite far away from the chelate ring. The inclination of the $p$-tolyl group of $124^{\circ}$ to the remaining part of the asymmetric unit (Table 3) has resulted in some close contacts, namely $\mathrm{C}(8) \cdots \mathrm{C}(7) 2 \cdot 32, \mathrm{C}(8) \cdots \mathrm{C}(9)$ 2.97 and $C(8) \cdots C u 3.30 \AA$, which affect the geometrical conformation of the chelate ring, especially in the neighbourhood of N . The result is that the bond lengths and interbond angles of the chelate ring are slightly different in the present case from the values found in (phenylsim) $)_{2} \mathrm{Cu}$ (Wei, Stogsdill \& Lingafelter, 1964) and in the pyridine solvate of (phenylsim) ${ }_{2} \mathrm{Cu}$ (Hall, SheatRumball \& Waters, 1968). $\mathrm{N}-\mathrm{C}(8), 1-45 \AA$, is similar to the value observed in other sim- Cu molecules having an aromatic ring substituent on N . A study of $\mathrm{N}-\mathrm{C}(8)$ lengths in different types of N -substituted sim- Cu molecules shows that molecules having a simple phenyl group or p-tolyl group as substituent (Table 4) have, in general, a length of about $1.45 \AA$ whereas those having a linear chain (Jain, Bindlish \& Kashyap, 1976), cyclohexyl ring, or ethylenediamine as substituent normally have a value above $1.47 \AA$. Thus N shows greater donation to the multibonding system in the presence of aromaticity around it.

The benzene ring retains its planarity. $C(3)$ has the maximum deviation of $0.013 \AA$ which is due to its inplane high thermal vibrations (Table 1). The benzene ring and the chelate ring are nearly coplanar with an angle of tilt of $3^{\circ}$. Omitting $\mathrm{C}(14)$, the deviations of other atoms of the $p$-tolyl group range from -0.02 to $0.04 \AA$. The Cu atom is farther out $(-0.41)$ and the N atom is out $(0 \cdot 12 \AA)$ in the opposite direction from the mean benzene plane.
$\mathrm{C}-\mathrm{H}$ lengths and bond angles involving H atoms are normal. Most of the bond lengths fall within the range $0 \cdot 90-1 \cdot 10 \AA$. There are no unusual contacts of H atoms with other atoms of the molecule.

The authors thank Dr C. J. Brown and Professor S. M. Mukherji for facilities and help, Dr M. B. Hursthouse for use of the ORTEP program, Dr S. K. Sikka for computer programs, CSIR for funds and the Computer Centres TIFR, Bombay, and the City of London Polytechnic, London, for computer work.
