# The Crystal Structure of Tetra(3-methylphenyl)tin 

By Anastas Karipides and Mary Oertel Department of Chemistry, Miami University, Oxford, Ohio 45056, USA

(Received 21 June 1976; accepted 2 August 1976)

#### Abstract

The crystal structure of tetra(3-methylphenyl)tin, $\left.\left(3-\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4}\right)\right)_{4} \mathrm{Sn}$, has been determined from threedimensional X-ray intensity data collected by counter methods on a computer-controlled diffractometer. The compound crystallizes in the tetragonal space group $I 4_{1} / a\left(C_{4 h}^{6}\right)$ with unit-cell dimensions $a=17.370$ (13), $c=8.285$ (9) $\AA$ and $Z=4$. The structure was refined by a full-matrix least-squares procedure to a conventional $R$ index of 0.031 for 1102 independent reflections. The crystal structure consists of discrete molecules with crystallographically imposed $\overline{4}$ symmetry, separated by normal van der Waals contacts. The observed $\mathrm{Sn}-\mathrm{C}$ and C (aryl)-C(methyl) distances are $2 \cdot 150$ (3) $\AA$ and 1.517 (5) $\AA$ respectively. The methyl group is twofold disordered. Rotation of the aryl ring plane from the $\mathrm{C}-\mathrm{Sn}-\mathrm{C}$ plane is $41^{\circ}$ which differs considerably from the value of $140.3^{\circ}$ predicted by a geometrical analysis [Maly \& Teply, Chem. Zvesti, (1953), 7, 553-562].

## Introduction

We have been interested in the crystal structures of aryl Group IV $a$ compounds of the type (aryl) ${ }_{4} \mathrm{M}$ in order to provide accurate structural parameters for use in a continuing study of the crystal packing and energetics of such molecular compounds. Of particular interest are those derivatives which retain molecular $\overline{4}$ symmetry in crystals of tetragonal symmetry (Kitaigorodsky, 1961; Karipides, Forman, Thomas \& Reed, 1974). This paper is concerned with the structural investigation of one such derivative, tetra(3-methylphenyl)tin (Teply \& Maly, 1953).

## Experimental

Tetra(3-methylphenyl)tin was prepared following the procedure described by Krause \& Becker (1920) and suitable crystals were obtained by recrystallization from ethanol. A single crystal, approximately $0.28 \times$ $0.28 \times 0.36 \mathrm{~mm}$, mounted along the longest dimension ( $\mathbf{c}^{*}$ ) was used. The tetragonal space group was uniquely determined to be $I 4_{1} / a$ from indexed Weissenberg photographs based on the systematic absences $h+$
$k+l=2 n+1$ for $h k l ; h(k)=2 n+1$ for $h k 0 ; l=4 n$ +1 for $00 l$. Accurate values of the unit-cell dimensions were obtained from the least-squares refinement of the angular settings of 12 reflections carefully measured on a Picker FACS-I automated diffractometer. The experimental density was determined by flotation in an aqueous solution of KI. The pertinent crystal data are presented in Table 1.

Three-dimensional X-ray intensity data were collected on the diffractometer already mentioned using Zr filtered Mo $K \alpha(\lambda=0.71069 \AA)$ radiation. 1327 reflections out to $50^{\circ}$ in $2 \theta$ were recorded by the $\theta-2 \theta$ scan technique with a $1^{\circ} \mathrm{min}^{-1}$ scan rate and a scan range of $2 \theta\left(\right.$ Mo $\left.K \alpha_{1}\right)-1.0^{\circ}$ to $2 \theta\left(\mathrm{Mo} K \alpha_{2}\right)+1.0^{\circ}$. A background count for 20 s at the start and end of each scan was taken. During the data collection the intensities of

Space group $I 4_{1} / a\left(C_{4 h}^{6}\right)$ $M_{r}=483.2 \mathrm{~g} \mathrm{~mol}^{-1}$ $F(000)=984$ $\mu($ Mo Ka $)=10.4 \mathrm{~cm}^{-1}$
$D_{o}=1.30 \mathrm{~g} \mathrm{~cm}^{-3}$
$D_{c}=1.284$
three standard reflections in different regions of reciprocal space were monitored after each 100 measurements and none showed any significant variation throughout the data collection.
The raw intensity data were assigned estimated standard deviations and reduced to values of $F_{o}$ and $\sigma\left(F_{o}\right)$ (assuming an 'uncertainty factor', $p=0.04$ ) in the manner previously described (Karipides et al., 1974). Absorption corrections were not applied. 1106 reflections had $I>\sigma(I)$ and these were used in the structure determination.

## Structure determination and refinement

The space group $I 4_{1} / a$ has 16 general positions which requires the four $\left(3-\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4}\right)_{4} \mathrm{Sn}$ molecules in the unit cell to lie on crystallographic special positions with 4 symmetry. There is, therefore, only one 3 -methylphenyl group in the asymmetric unit. The seven independent C atoms were located from a difference Fourier map phased by the Sn atom placed at the origin. The trial structure was initially refined by a fullmatrix least-squares procedure by assuming isotropic thermal motion for all atoms. At this stage a difference electron density map revealed a twofold rotational disorder of the H atoms of the methyl group. This disorder of the methyl group was accommodated by including the six experimentally found H atoms in the structure factor calculations each at half weight. The positions of these H atoms were adjusted so that the individual $\mathrm{C}-\mathrm{H}$ bond lengths equalled $1.08 \AA$ but their angular orientations were kept intact at those found from the difference Fourier map. This adjustment of the $\mathrm{C}-\mathrm{H}$ distances to their true internuclear value is required in order to later establish the accurate intermolecular contact distances involving H atoms (Churchill, 1973). The aryl ring H atoms were introduced by placing them in theoretical positions assuming that the $\mathrm{C}-\mathrm{H}$ bond (length fixed at $1.08 \AA$ ) bisects the calculated $\mathrm{C}-\mathrm{C}-\mathrm{C}$ angle. Also at this stage careful examination of the $\left|F_{o}\right|$ and $\left|F_{c}\right|$ list revealed that the $020,200,121$, and 321 reflections were severely affec-
ted by secondary extinction; these reflections were not included in subsequent calculations.

The structure was further refined by full-matrix least-squares calculations assuming anisotropic motion for the Sn and C atoms. All H atoms were assigned the average isotropic temperature factors calculated from the anisotropic thermal parameters of the C atoms to which they were attached; however, H atom parameters were not varied. The quantity minimized was $\Sigma w\left(\left|F_{o}\right|-\left|F_{c}\right|\right)^{2}$ where the weight applied to each observation was taken to be $1 / \sigma^{2}\left(F_{o}\right)$. New H parameters were calculated after each least-squares run. The final refinement resulted in a conventional $R$ value, $\Sigma\left(\left|F_{o}\right|-\left|F_{c}\right|\right) / \Sigma\left|F_{o}\right|$, of 0.031 and a weighted $R$ value, $\left[\Sigma w\left(\left|F_{o}\right|-\left|F_{c}\right|\right)^{2} / \Sigma w\left|F_{o}\right|^{2}\right]^{1 / 2}$, of 0.036 . The final standard deviation in an observation of unit weight was 1.34 . There were 1102 data and 66 variable parameters yielding a data:parameter ratio of 16.7:1. An analysis of $w\left(\left|F_{o}\right|-\left|F_{c}\right|\right)^{2}$ as a function of $\left|F_{o}\right|$ or $\sin \theta / \lambda$ revealed no dependence on these quantities suggesting that the chosen weighting scheme was reasonable. A final difference Fourier map was featureless.

The neutral atomic scattering factors for Sn (corrected for $\Delta f^{\prime}$ and $\Delta f^{\prime \prime}$ ) and C were taken from Cromer \& Mann (1968) and Cromer \& Liberman (1970). The

H scattering factors were those given by Stewart, Davidson \& Simpson (1965). Calculations were carried out on IBM 370/168 and AMDAHL $470 \mathrm{~V} / 6$ computers with programs previously described (Karipides et al., 1974). The final atomic positional and thermal parameters and their standard deviations are given in Tables 2 and 3.*

## Description of the structure and discussion

The molecular symmetry of tetra(3-methylphenyl)tin in the crystalline state is 4 . Views of the molecular structure, unit-cell contents and atom-numbering scheme are presented in Figs. 1 and 2. Intramolecular bond distances and angles are given in Table 4.

The observed $\mathrm{Sn}-\mathrm{C}(1)$ distance is 2.150 (3) $\AA$ which is in agreement with $2 \cdot 147$ (6) and $2 \cdot 14$ (1) $\AA$ found in tetra(4-methylphenyl)tin (Karipides \& Wolfe, 1975) and tetraphenyltin (Chieh \& Trotter, 1970; Ahmed \& Aleksandrov, 1970) respectively. The aryl C-C distances (average $1.392 \pm 0.003 \AA$ ) and the aryl-methyl distance, $\mathrm{C}(4)-\mathrm{C}(7) 1.517$ (5) $\AA$, are normal. The aryl ring is planar; the equation of the unit-weighted leastsquares plane fitted to the six ring C atoms is 0.8276 X $+0.1667 Y-0.5360 Z+0.0100=0$. The largest deviation of any of the six C atoms from this plane is 0.006 $\AA$. The Sn and methyl C atoms are also in this plane

[^0]

Fig. 1. A projection of the structure on the $x y$ plane viewed along the $\overline{4}$ axis.
with 0.010 and $0.028 \AA$ displacements respectively. The phenyl ring, however, is distorted from idealized $D_{6 n}$ symmetry in a manner summarized by Domenicano, Vaciago \& Coulson (1975a,b). In particular the apical $\mathrm{C}(2)-\mathrm{C}(1)-\mathrm{C}(6)$ angle is 118.4 (3) ${ }^{\circ}$ which compares with $116.4(6)^{\circ}$ for the corresponding angle in the isomeric tetra(4-methylphenyl)tin (Karipides \& Wolfe, 1975). This approximately $2^{\circ}$ increase in the apical $\mathrm{C}-\mathrm{C}-\mathrm{C}$ angle in the meta substituted compound is consistent with the predicted skeletal deformations of disubstituted benzenes (Domenicano, Vaciago \& Coulson, 1975a).

The methyl group is twofold disordered with the two orientations represented by atoms $\mathrm{H} 1(\mathrm{C} 7), \mathrm{H} 2(\mathrm{C} 7)$, $\mathrm{H} 3(\mathrm{C} 7)$ and $\mathrm{H} 4(\mathrm{C} 7), \mathrm{H} 5(\mathrm{C} 7), \mathrm{H} 6(\mathrm{C} 7)$ respectively. The aryl ring plane makes an angle of $92^{\circ}$ with the plane $\mathrm{H} 1(\mathrm{C} 7)-\mathrm{C}(7)-\mathrm{C}(3)$ which along with the dihedral

angles $\mathrm{H} 2(\mathrm{C} 7)-\mathrm{C}(7)-\mathrm{C}(3)-\mathrm{C}(2) 149^{\circ}$, $\mathrm{H} 3(\mathrm{C} 7)-\mathrm{C}(7)$ $-\mathrm{C}(3)-\mathrm{C}(2) 33^{\circ}, \mathrm{H} 4(\mathrm{C} 7)-\mathrm{C}(7)-\mathrm{C}(3)-\mathrm{C}(2)-148^{\circ}$, $\mathrm{H} 5(\mathrm{C} 7)-\mathrm{C}(7)-\mathrm{C}(3)-\mathrm{C}(2) 93^{\circ}, \mathrm{H} 6(\mathrm{C} 7)-\mathrm{C}(7)-\mathrm{C}(3)-$ $\mathrm{C}(2)-33^{\circ}$ specifies the conformation of the disordered methyl group.

The crystal structure consists of discrete (3$\left.\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4}\right)_{4} \mathrm{Sn}$ molecules separated by normal van der Waals distances. The shortest $\mathrm{C} \cdots \mathrm{H}$ intermolecular distance in the structure is $\mathrm{C}(4) \cdots \mathrm{H}(4)\left(\frac{1}{2}+y, \bar{x}, z-\frac{1}{4}\right)$ $2.73 \AA$ and there are no non-bonded intramolecular contacts less than $3 \cdot 18 \AA$. The shortest $\mathrm{H} \cdots \mathrm{H}$ contacts all involve methyl H atoms: $\underline{\mathrm{H}}(6) \cdots \mathrm{H} 1(\mathrm{C} 7)(\bar{y}, x$ $\left.-\frac{1}{2}, z-\frac{3}{4}\right) 2 \cdot 54 ; \mathrm{H}(4) \cdots \mathrm{H} 2(\mathrm{C} 7)\left(\bar{y}, x-\frac{1}{2}, z-\frac{3}{4}\right) 2 \cdot 59$; $\mathrm{H}(6) \cdots \mathrm{H} 4(\mathrm{C} 7)\left(\bar{y}, x-\frac{1}{2}, z-\frac{3}{4}\right) 2.67 \AA$, although these intermolecular distances are appreciably longer than the 2.0 to $2.4 \AA$ range generally accepted as normal $\mathrm{H} \cdots \mathrm{H}$ van der Waals distances (Bondi, 1964). These long-range and weak methyl H interactions lead to a more flexible intermolecular environment about the methyl group and, perhaps, account for the observed disorder. This situation is in contrast to that found in tetra(4-methylphenyl)tin where the para substituted methyl group is rigidly oriented in the crystal (Karipides \& Wolfe, 1975).

Maly \& Teply (1953) attempted a geometrical analysis of the crystal structure of tetra(3-methylphenyl)tin. Their structure, determined theoretically by optimizing the intermolecular van der Waals contacts of selected non-bonded atom-pair interactions, is not in agreement with the crystal structure reported here. For example, the aryl ring plane in our experimental structure is twisted $41^{\circ}$ from the valency angle plane $C(1)-$ $\mathrm{Sn}-\mathrm{C}(1)(\bar{x}, \bar{y}, \bar{z})$ whereas in the structure predicted by Maly \& Teply (1953), the corresponding angle is $140.3^{\circ}$. In each case the indicated conformation angle is positive for a clockwise rotation looking from the aryl ring to the Sn atom. These results emphasize that extreme caution must be exercised in predictions of crystal structures using such geometrical analyses based on only a relatively few non-bonded interactions (Karipides \& Haller, 1972). Clearly, a preferable procedure is to minimize the total lattice (packing) energy which includes the contributions of all intermolecular interactions.

The crystal structures of a number of tetra(aryl)tin compounds have been reported which crystallize in tetragonal space groups and include tetraphenyltin, $P \overline{4} 21 c$, (Chieh \& Trotter, 1970; Ahmed \& Aleksandrov, 1970), tetrakis(pentafluorophenyl)tin, $/ 4_{1} / \underline{a}$, (Karipides et al., 1974), tetra(4-methylphenyl)tin, $I \overline{4}$, (Karipides \& Wolfe, 1975), tetra(4-methoxyphenyl)tin, $I \overline{4}$, (Ismailzade, 1958) and tetra(3-methylphenyl)tin, $I 4_{1} / a$, described in this paper. Of particular interest is the constancy of molecular $S_{4}$ symmetry in all of these derivatives. Since the nature of the aryl substituent and space groups and hence molecular packing vary considerably, the occurrence of the same molecular sym-
metry strongly suggests that the molecular conformation of $S_{4}$ symmetry is energetically favored in crystals of tetragonal symmetry. This idea is consistent with recent studies on the preferred conformations of tetra(aryl)methanes and -silanes (Hutchings, Andose \& Mislow, 1975; Robbins, Jeffrey, Chesick, Donohue, Cotton, Frenz \& Murillo, 1975; Ahmed, Kitaigorodsky \& Mirskaya, 1971; Glidewell \& Sheldrick, 1971).

Tetra(3-methylphenyl)tin is the first example of a tetra(aryl) Group IV $a$ compound involving an unsymmetrically substituted phenyl group. For such a species with molecular $S_{4}$ symmetry there are two diasteromeric conformers which are possible corresponding to the structures where the methyl group is relatively nearest the plane through the center of the molecule and normal to the $\overline{4}$ axis (exo) or relatively furthest from the same plane (endo). The observed conformation in tetra(3-methylphenyl)tin is exo. Although empirical force-field calculations on the static stereochemistry of isolated molecules of meta-substituted tetra(aryl) derivatives were not reported, the exo conformation has been shown to be the most stable in similar studies of tetra(2-methylphenyl)methane and -silane (Hutchings, Nourse \& Mislow. 1974: Hutchings, Andose \& Mislow, 1975).

# The Structure of an Antihistamine: Cyproheptadine Hydrochloride Sesquihydrate 

By BjøRn Birknes<br>Department of Chemistry, University of Bergen, N-5014 Bergen, Norway

(Received 6 July 1976; accepted 7 August 1976)

#### Abstract

Cyproheptadine hydrochloride sesquihydrate $\left(\mathrm{C}_{21} \mathrm{H}_{21} \mathrm{~N}\right.$. HCl. $\left.1 \frac{1}{2} \mathrm{H}_{2} \mathrm{O}\right)$ is orthorhombic, space group Fdd2, with $a=43.53(1), b=18.226(6), c=9.587$ (4) $A, Z=16$. One water molecule is situated on a twofold axis. The tricyclic part of the molecule is folded and the angle between the planes of the two benzene rings is $124 \cdot 1^{\circ}$. The piperidine ring has a chair and the seven-membered ring a boat conformation. The cyproheptadine molecule possesses $C_{s}$ symmetry within the limits of error. The structure was refined to an $R$ of $3.9 \%$.

## Introduction

Several substances are known to antagonize both histamine and serotonin, among which are various phenothiazine derivatives (Gyermek, Lazar \& Czák, 1956; Parratt \& West, 1958). None of these compounds is, however, particularly outstanding as an antagonist of serotonin. A relatively new antihistamine, cyproheptadine hydrochloride or 4 -( 5 H -dibenzo $[a, d]$ -cycloheptene- 5 -ylidene)-1-methylpiperidine, is unique in that its antagonism towards both histamine and serotonin is of a high order. In addition cyproheptadine has some weak antropene-like activity and possesses mild central depressing properties (Stone, Wenger, Ludden, Stavorski \& Ross, 1961). Clinically, cyproheptadine has been found to be effective in the treatment of various allergies. The most prominent side effect is drowsiness (Miller \& Fishman, 1961).
The structure of cyproheptadine resembles in certain respects the phenothiazine antihistamines. It also bears some resemblance to lysergic acid derivatives, which are good serotonin antagonists in that they possess an $N$-substituted heterocyclic ring. In comparison with simpler indole-type serotonin antagonists, however, there is no structural resemblance. The determination of this crystal structure was undertaken as part of a general study of antihistaminic drugs.

## Crystal data

The powdered substance was obtained from Merck, Sharp \& Dohme. Crystals of $\mathrm{C}_{21} \mathrm{H}_{21} \mathrm{~N} . \mathrm{HCl} .1 \frac{1}{2} \mathrm{H}_{2} \mathrm{O}$,
grown from ethanol, are colourless prisms of rhombic cross-section; space group Fdd2, with $a=43.53$ (1), $b$ $=18.226$ (6), $c=9.587(4) \AA, V=7606$ (4) $\AA^{3}, Z=$ $16, D_{m}=1.215, D_{x}=1.225 \mathrm{~g} \mathrm{~cm}^{-3}, \mu(\mathrm{Mo} K \alpha)=2.16$ $\mathrm{cm}^{-1}$.

## Experimental

A crystal $0.41 \times 0.41 \times 0.37 \mathrm{~mm}$ was used throughout the data collection, mounted along c. 2209 reflexions, including 56 with negative intensity, were measured on a paper-tape-controlled Siemens AED diffractometer by the five-value scan technique ( $\theta \leq$ $27^{\circ}$ ). $2 \theta$ values for several high-order reflexions were measured, and the cell dimensions found by leastsquares calculations.

Lp corrections were applied, but absorption corrections were ignored.

Scattering factors computed from numerical Har-tree-Fock wave functions (Cromer \& Mann, 1968) were used for the non-hydrogen atoms; for H , the values given by Stewart, Davidson \& Simpson (1965) were used.

## Structure determination and refinement

The structure was solved by direct methods with MULTAN 74 (Main, Woolfson, Lessinger, Germain \& Declercq, 1974). Phase determination for 300 reflexions with $E \geq 1.41$ was carried out with a weighted
