## Molecular Compounds and Complexes.

# X.* The Crystal Structure of the $\pi$-Molecular Compound 

 Benzo[c]phenanthrene-2,3-Dichloro-5,6-dicyanobenzoquinoneBy J. Bernstein and H. Regev $\dagger$<br>Department of Chemistry, Ben-Gurion University of the Negev, Beersheva, Israel<br>and F. H. Herbstein<br>Department of Chemistry, Technion-Israel Institute of Technology, Haifa, Israel

(Received 17 September 1976; accepted 13 November 1976)

#### Abstract

The influence of $\pi$-molecular compound formation on the deviations from planarity of the overcrowded aromatic molecule benzo[c|phenanthrene has been studied by determining the crystal structure of benzolc|-phenanthrene-2,3-dichloro-5,6-dicyanobenzoquinone $a=10.953$ (2), $b=16.090$ (3), $c=13.827$ (3) $\AA . \beta=$ $122.63(1)^{\circ}$; space group $P 2_{1} / c ; Z=41$. The structure was solved by direct methods and refined to $R=$ 0.065 for 3385 observed reflexions. Stacks with alternating donor and acceptor molecules extend in the $\mathbf{c}$ direction. The acceptor molecule takes on two orientations, with population ratio $\sim 4: 1$. Comparison of the structures of the benzo [c|phenanthrene molecule here and in its pure crystals shows that it is significantly less distorted from planarity in the present molecular compound, but that bond lengths and angles remain practically unchanged. The diminished distortion from planarity may be due to the donor-acceptor interaction.

## 1. Introduction

Most crystallographic studies of $\pi$-molecular compounds have been made on systems in which the donor

[^0]and acceptor moieties are essentially rigid, planar molecules. Comparison of the molecular geometries (especially bond lengths and angles) of the components in the crystalline molecular compound with those found in the structures of the pure components has consistently shown virtually no change upon molecularcompound formation. This is not surprising since the forces required to alter these geometrical features are
larger than those involved in molecular-compound formation.

In the large majority of the $\pi$-molecular compounds studied to date there is some form of infinite stack of alternating donor and acceptor molecules, strongly suggesting the presence of a principal component of the charge-transfer forces perpendicular to the molecular planes. For some non-planar donors (e.g. hexahelicene, phenothiazine, dibenzol $g, p$ lchrysene* ${ }^{*}$ and benzo $[c]$ phenanthrene) this component may be sufficient to induce a change in the conformation of the molecule, in particular in its deviations from planarity.

The $\pi$-molecular compound of benzolclphenanthrene (BP) and 2,3-dichloro-5,6-dicyanobenzoquinone (DDQ) is an attractive model system for examining the effect of molecular-compound formation on the degree of distortion of a non-planar component. The structure of the donor has been studied (Herbstein \& Schmidt, 1954; Hirshfeld, Sandler \& Schmidt, 1963) and thus provides a standard geometry for comparison with that found in the molecular compound.

## 2. Experimental

Crystals of the $1: 1$ molecular compound suitable for X-ray studies were grown by vapour diffusion of $n$ pentane into a chloroform solution of approximately equimolar quantities of the two components (Stout \& Jensen, 1968). The crystals were dark, opaque prisms elongated along $\mathbf{c}$.

The space group ( $P 2 / 1 c$ ) and approximate cell dimensions were obtained from photographs. With the appropriate transformation they conform to those previously reported in the non-standard space group $B 2_{1} / c$ (Herbstein, 1971). More accurate cell dimensions (Table 1) were obtained from a least-squares fit of fourcircle diffractometer measurements of $2 \theta$ values at $20^{\circ} \mathrm{C}$ for 15 reflexions with $47.5^{\circ} \leq 2 \theta \leq 50.73^{\circ}$ (Mo $K r)$.

A prism $0.18 \times 0.34 \times 0.50 \mathrm{~mm}$ was mounted on a Syntex $P \overline{1}$ autodiffractometer with $\mathbf{c}$ nearly parallel to

> * Also called tetrabenznaphthalene.

$D_{x}=1.471$
$F(000)=928$
$\mu(\mathrm{CuKr})=30.7 \mathrm{~cm}^{-1}$
the $\varphi$ axis of the diffractometer. Intensities were measured with graphite-monochromatized $\mathrm{Cu} K \alpha$ radiation and the $\theta-2 \theta$ scanning technique. The variable scanning speed employed ranged from 2 to $24^{\circ} \mathrm{min}^{-1}$, according to a rapid prescan of the peak intensity of the current reflexion. A total average decrease of $4 \%$ in the intensities of the four monitor reflexions was taken into account in the data reduction.

The intensities of 3852 unique reflexions (about $85 \%$ of the Cu sphere) were measured for $\sin \theta / \lambda<0.60 \AA^{-1}$; 3153 of these, whose measured intensity was more than $2 \cdot 5 \sigma(I)$, were considered observed. Corrections were made for Lorentz and polarization factors and for absorption (Coppens, Leiserowitz \& Rabinovich, 1965). The last correction was made after nine cycles of refinement. Intensities were assigned variances $\sigma^{2}(I)$, according to counting statistics and a factor to account for instrumental instability, i.e. $\sigma^{2}(I)=\mid \sigma_{c}^{2}(I)+$ $\left.(0.03 I)^{2}\right]$, where $\sigma_{c}^{2}(I)$ is the variance based on counting statistics.

## 3. Strutcture determination and refinement

### 3.1. Solution of the structure

The intensities were placed on an approximately absolute scale by Wilson's (1942) method, and normalized structure factor magnitudes $(E)$ were derived. The structure was solved with MULTAN (Germain, Main \& Woolfson, 1971). From 326 reflexions with $|E|>1 \cdot 68,16$ sets of signs for 322 reflexions were obtained. The set chosen for calculation of the $E$ map was that with the highest absolute figure of merit (1.028) and the lowest residual ( $34 \cdot 17$ ). The resulting map gave a clear view of the entire structure except in the region of the $-\mathrm{C} \equiv \mathrm{N}$ groups, where only weak and diffuse peaks appeared. The four atoms in these two groups were added on the basis of chemical considerations.

### 3.2. Refinement

The structure was refined in the block-diagonal approximation, the blocks corresponding to the two molecular moieties. First, coordinates of non-hydrogen atoms and an overall temperature factor were refined for reflexions with $\sin \theta / \Lambda<0.4 \AA^{-1}$. Individual isotropic temperature factors were then introduced $\left(\sin \theta / \lambda<0.5 \AA^{-1}\right)$. At this stage the $\mathrm{C} \equiv \mathrm{N}$ bonds were very short ( $0.95 \AA$ ). Suspecting that this was an anomaly of the refinement we shifted the two N atoms to positions calculated on the basis of more reasonable $\mathrm{C} \equiv \mathrm{N}$ lengths. Two additional cycles resulted in a shortening of the $\mathrm{C} \equiv \mathrm{N}$ lengths to the value obtained previously. Anisotropic temperature factors were then introduced ( $\sin \theta / \lambda<0.52 \AA^{-1}$ ). Expected H positions were calculated and were included in the following
cycles (observed reflexions and the unobserved for which $F_{c}>k F_{o}$ on the previous cycle). In the last three cycles the three strongest reflexions ( 020,110 and $\overline{1} 14$ ) were given zero weight because of extinction. The temperature factors of $\mathrm{H}[\mathrm{BPC} C(1)]$ and $\mathrm{H}[\mathrm{BPC}(12)]$ were fixed at $0.04 \AA^{2}$ as the previous cycles had yielded excessively large shifts for them. The final $R$ is 0.065 ( $R_{w}$ $=0.028$ ) for the 3385 observed reflexions and those for which $F_{c}>k F_{o}$. For all the reflexions (3852, iscluding unobserved) $R=0.068$. The goodness-of-fit is 3.17 , suggesting that the weighting scheme was not ideal. The function minimized was $\Sigma w\left(\left|k F_{o}\right|^{2}-\left|F_{c}\right|^{2}\right)$, where $w=1 \cdot 0 / \sigma^{2}\left(F_{o}^{2}\right)$. Scattering factors were taken from In-

Fig. 1. Difference map in the DDQ plane, contours at intervals of 1 e $\AA^{-3}$. The heavy line shows the zero contour and the broken line the 0.5 e $\AA^{-3}$ contour; other contours are at intervals of 1 e $\AA^{-3}$ (dotted lines show negative regions). The coordinate system from the best-plane calculation (\$4.2.2) is shown together with the principal orientation of the DDQ molecule (the structure factors used in the difference synthesis were calculated on the basis of this model). The peaks between C and N atoms of the CN groups are ascribed to Cl atoms of the minor orientation. The positions to which the N atoms refined when disorder was ignored are shown by dots in $N(7)$ and $N(8)$. The dashed line from $\mathrm{Cl}(3)$ goes up to $\mathrm{H}[\mathrm{BP} \mathrm{C}(5)]^{\mathrm{iii}}$ and that from $\mathrm{Cl}(2)$ goes down to $\mathrm{H}[\mathrm{BP} \mathrm{C}(4)]^{\text {iv }}$ (symmetry codes of molecules are given in Table 3).

(a)

(b)

Fig. 2. (a) Projection of structure on the (100) plane. The two reference molecules (coordinates in Table 2) are designated (i) (the symmetry code is in Table 3). The two enantiomers of BP are designated $A$ and $A^{\prime}$. (b) Projection of part of the structure on (010).

Fig. 3. Description of crystal structure in terms of molecular sheets (the symmetry code is in Table 3). (a) Sheet of DDQ molecules at $z \sim \frac{1}{4}$, projected onto (001). (b) Packing of nearest BP molecules around the DDQ reference molecule, viewed normal to the mean plane of DDQ. The BP molecules above and below the reference DDQ molecule have been omitted for clarity.
ternational Tables for X-ray Crystallography (1962). The least-squares program is a local version of $O R F L S$ (Busing, Martin \& Levy, 1962).

At the end of the refinement the $\mathrm{C} \equiv \mathrm{N}$ lengths remained significantly shorter than the accepted value of 1.13 (1) $\AA$ (Larsen, Little \& Coppens, 1975). A difference map was calculated in the DDQ least-squares plane, with parameters of the last cycle and N atom coordinates calculated for a linear $\mathrm{C}-\mathrm{C} \equiv \mathrm{N}$ group and a $\mathrm{C} \equiv \mathrm{N}$ length of $1.133 \AA$ (Fig. 1). The map shows peaks of about 2 e $\AA^{-3}$ between DDQ C(7) and DDQ $\mathrm{N}(7)$, and between DDQ C(8) and DDQ N(8). Another peak of about $0.5 \mathrm{e}^{\AA^{-3}}$ appeared between DDQ C(3) and the Cl atom bonded to it.

(a)
(c)

(b)

Fig. 4. Overlap diagram of the molecules in a stack, viewed pairwise to avoid complicating the diagrams. The anticlock wise progression $(a)-(d)$ proceeds up the stack axis, i.e. in the $[001]$ direction. The axial system of the reference BP molecule, whose origin is located at the molecular centre of gravity, is shown in each of the diagrams for reference and some of the atoms are numbered for convenience. All the molecules are projected onto the reference plane of the reference BP molecule. (a) Reference molecules, BP below at $z \sim 0, \mathrm{DDQ}$ above at $z \sim 3.4 \AA$. (b) The reference DDQ molecule, below, at $z \sim 3.4 \AA$ and the BP molecule related to the reference BP molecule by the $c$ glide, above, at $z \sim 6.8 \AA$. (c) The two molecules related to the reference molecules by the $c$ glide plane, BP below at $z \sim 6.8 \mathrm{~A}$, DDQ above at $z \sim 10.2 \AA$. (d) The DDQ molecule derived from the reference molecule by the $c$ glide, below, at $z \sim 10.2 \AA$ and the reference BP molecule translated by $c$, above, at $z \sim 13.8 \AA$.

On the basis of this map it is possible to propose a model for static orientational disorder which accounts for the shortened $\mathrm{C} \equiv \mathrm{N}$ lengths. According to this model the DDQ molecules take up two orientations. The principal orientation is that shown in the packing diagrams (Figs. 2, 3 and 4). The second is related to the principal orientation by a non-crystallographic twofold axis in the DDQ plane (or alternatively perpendicular to it) so that at some molecular sites Cl atoms replace CN groups and vice versa. As a result, Cl atoms contribute additional electron density between C and N atoms in the space-averaged structure. The occupancy factor of the principal orientation was estimated, from the difference density, to be 0.8 .

Atomic coordinates from the final least-squares cycle are listed in Table 2.*

[^1]Table 2. Final fractional coordinates $\left(\times 10^{4}\right.$, for $H$ $\times 10^{3}$ )
E.s.d.'s in parentheses are in units of the least significant digits. H atoms are numbered according to the C atoms to which they are bonded.

## 4. Results and discussion

### 4.1. Crystal structure

The projections on the (100) and (010) planes (Fig.
2 ) show the two components arranged in an alternating
array in mixed stacks. The angle between the plane of the DDQ molecule and the reference plane of BP (see $\$ 4.2$ for definition) is $6 \cdot 2^{\circ}$; because of the nonplanarity of BP the exact value of this angle has little physical significance. The component molecules lie approximately in $\{\overline{1} 14\}$ planes; the reflexions from these planes are very strong and are accompanied by intense diffuse scattering. The unit cell contains two stacks which are related to one another by the twofold screw axis; the stacks are approximately hexagonally close-packed (Fig. 3). Shorter intermolecular distances are listed in Table 3 and some of these are shown in Fig. 3.

The overlap diagram is shown in Fig. 4. Chemically identical molecules along a stack are related by the operation of the $c$ glide plane. A particular DDQ molecule is located above one phenanthrene portion of the neighbouring BP molecule; the next DDQ molecule in the stack takes up an analogous position and orientation with respect to the other phenanthrene portion of the BP molecule sandwiched between them, and so on, in alternating fashion, along the stack.

Because the stacks are not shifted with respect to one another along the [001] axis, the structure can also be described in terms of alternating sheets of BP and DDQ molecules. Two views based on this description are shown in Fig. 3. The packing of both BP and DDQ molecules in their respective sheets is rather loose and interstack distances are longer than intrastack dis-

Table 3. Intermolecular distances ( $\AA$ )
Distances involving N atoms are excluded because of the disorder. Criteria for inclusion in table: $d(\mathrm{C} \cdots \mathrm{C}), d(\mathrm{C} \cdots \mathrm{O}) \leq 3.30$ : $d(\mathrm{C} \cdots \mathrm{H}), d(\mathrm{O} \cdots \mathrm{H}) \leq 2.95 ; d(\mathrm{H} \cdots \mathrm{H}) \leq 2.82 \AA$.

| (iv) | $1+x \cdot \frac{1}{2}-1 \cdot \frac{1}{2}+z$ | (ix) | -x. $\frac{1}{2}+\cdots \frac{1}{2}-z$ |
| (v) | $1-x, \frac{1}{2}+1, \frac{1}{2}-2$ | (x) | $1-x .10+1.15$ |

tances; thus a description in terms of stacks is physically preferable to that in terms of sheets. In the sheets of DDQ molecules there are short distances of $3.21 \AA$ between chains of molecules along [010] (Fig. $3 a$ ); there are two chains per unit cell at $z \sim \frac{1}{4}$ and $\sim \frac{3}{4}$. Comparison with other structures is made in the discussion (§5).

The diagrams of Fig. 3 are drawn for the principal orientation of the DDQ molecule but the minor orientation can be accommodated without necessitating a large relaxation of molecular positions or orientations. If the reference DDQ molecule ( i$)^{*}$ is replaced by a DDQ molecule in the minor orientation ( $i^{\prime}$ ) but the other molecules are left unchanged then $d\left[\mathrm{~N}(8)^{i} \cdots \mathrm{~N}(8)^{\text {iii }}\right]$ is 2.7 and $d\left[\mathrm{~N}(8)^{\prime \prime} \ldots \mathrm{Cl}(3)^{\text {viii }}\right]$ is 2.9 $\AA . \dagger$

### 4.2. Molecular structure

4.2.1. Benzo[c]phenanthrene. Although the molecule (Fig. 5) is clearly non-planar, a mean reference plane may be defined through $\mathrm{C}(3), \mathrm{C}(10)$, $\mathrm{C}(14), \mathrm{C}(16), \mathrm{C}(17)$ and $\mathrm{C}(18)$. The equation of this plane is $0.26398 X^{\prime}-0.02500 Y^{\prime}-0.96420 Z^{\prime}+$ $1.062 \AA=0$, where $X^{\prime}, Y^{\prime}$ and $Z^{\prime}$ are coordinates in $\AA$ in an orthogonal system, related to the crystal system by the transformation matrix

$$
\left(\begin{array}{ccc}
a & 0 & c \cos \beta \\
0 & b & 0 \\
0 & 0 & c \sin \beta
\end{array}\right)
$$

The structure of BP at room temperature has been reported by Hirshfeld, Sandler \& Schmidt (1963). As in other charge-transfer molecular compounds, significant differences in bond lengths and angles are not found between the molecules in the BP crystals and in BPDDQ. Two bonds $[\mathrm{C}(12)-\mathrm{C}(16)$ and $\mathrm{C}(2)-\mathrm{C}(3)]$ are 0.023 and $0.030 \AA$ (about $4 \sigma$ ) shorter in the molecular compound, while three angles $[\mathrm{C}(18)-\mathrm{C}(1)-\mathrm{C}(2)$, $\mathrm{C}(11)-\mathrm{C}(12)-\mathrm{C}(16)$ and $\mathrm{C}(16)-\mathrm{C}(15)-\mathrm{C}(8)]$ are larger by $2^{\circ}(4 \sigma)$. The non-bonded intramolecular H[BP $\mathrm{C}(1)]-\mathrm{H}[\mathrm{BP} \mathrm{C}(12)]$ distance between the overcrowded atoms ( $2.03 \AA$ ) is equal in the two structures.

The BP molecule is, however, significantly less distorted from planarity in BP-DDQ than in BP itself. The degree of distortion may be measured by the deviations of atoms from the molecular plane (as defined above) and by the torsion angles about bonds, particularly those through which rings are fused. Most of the deviations from the reference plane in the molecular compound are significantly smaller than those found in BP itself (Fig. 5c); the largest difference is $0.12 \AA$ (17o

[^2]

Fig. 5. (a) Bond lengths ( $\AA$ ) for BP. E.s.d.'s are $\sim 0.007 \AA(\sim 0.07$ $\AA$ for $\mathrm{C}-\mathrm{H}$ bonds). (b) Bond angles $\left({ }^{\circ}\right)$ for BP. E.s.d.'s are $\sim 0.4^{\circ}$. (c) Deviations from planarity (units of $10^{-2} \AA$ ) for $B P$, in BP-DDQ, compared with the deviations for BP |Hirshfeld et al. (1963), in parenthesesl. The reference plane is defined with respect to the atoms shown as dots.
of bond lengths). Furthermore, the torsion angles (Table 4) approach the values for a hypothetical planar molecule ( 0 and $180^{\circ}$ ) more closely in BP-DDQ than in BP itself; the largest change is $4.6^{\circ}$ while the r.m.s. deviation from the ideal values for a planar molecule is

Table 4. Torsion angles $\left(^{\circ}\right.$ ) in the BP molecule in BP itself (Hirshfeld et al., 1963) and in BP-DDQ (present work) Atom numbers refer to carbon atoms (hydrogens not considered). Equivalent torsion angles are those that would be equal were the molecular symmetry exactly $C_{2}$.

Table 4 (cont.)
Summary of conclusions

|  | R.m.s. deviation <br> from equality of <br> equivalent | R.m.s. deviation <br> of torsion <br> angles from |
| :--- | :---: | :---: |
| Molecule | 1.04 | 0 or $\pm 180^{\circ}$ |
| BP | 0.59 | 8.76 |
| BP in BP-DDQ |  | 7.45 |

The values in the first column give a measure of the deviation of the molecule from the ideal symmetry $C_{2}$, in the second a measure of the deviation of the molecule from planarity.
reduced from 8.76 to $7.45^{\circ}$. We also note that the BP molecule in BP-DDQ approaches more closely the ideal symmetry $C_{2}$ than in BP itself. Thus the conformation of benzo $[c]$ phenanthrene has undergone a significant change upon formation of the molecular compound. The directional properties of these changes are consistent with those of charge-transfer forces and we attribute the alteration in geometry to these.
4.2.2. 2,3-Dichloro-5,6-dicyanobenzoquinone. Complete determination of the geometry of DDQ (Fig. 6) was not possible because of the disorder; $\mathbf{N}$ atoms are not included in the following discussion. The molecular dimensions are very similar to those of chloranil (van Weperen \& Visser, 1972) and a number of chlorinated $p$-benzoquinones (Rees, 1970b); the only noteworthy difference is in the value of $d(\mathrm{C}-\mathrm{Cl})$ where we obtain 1.736 (4) compared to a mean value of $1.715 \AA$ for the other molecules. However, the presence of disorder casts some doubt on the significance of our value.

Fig. 6. (a) Bond lengths $(\AA)$ and (b) angles $\left(^{\circ}\right)$, and deviations from planarity (units of $10^{-3} \AA$ ) for DDQ. E.s.d.'s are $\sim 0.007 \AA$ for $\mathrm{C}-\mathrm{C}, \sim 0.006 \AA$ for $\mathrm{C}-\mathrm{O}$ and $\sim 0.005 \AA$ for $\mathrm{C}-\mathrm{Cl}$ bonds, and for angles $\sim 0.4^{\circ}$.

The DDQ molecule is essentially planar. The equation of the least-squares plane of the reference molecule, not including $\mathrm{C} \equiv \mathrm{N}$ groups, is $0.30214 X^{\prime}+$ $0.07598 Y^{\prime}-0.95023 Z^{\prime}+3.908 \AA=0\left(X^{\prime}, Y^{\prime}, Z^{\prime}\right.$ have the same meaning as above). Small but significant differences are found in the deviations of the O and Cl atoms from the mean plane of the C atoms in the three similar molecules: chloranil, 2,3-dichlorobenzoquinone (Rees, 1970a) and DDQ [however, it should be noted that the largest of these displacements is only $0.085 \AA$ ( O of chloranil)]. Rees and van Weperen \& Visser suggest that these displacements arise from steric interactions between adjacent non-bonded atoms. Their virtual absence in DDQ suggests that formation of the molecular compound may influence the detailed structure of DDQ, as we have found above for BP. In support of this suggestion we note that chloranil has been found to be planar in its molecular compounds with pyrene (Prout \& Tickle, 1973) and with 9-methylanthracene (Tickle \& Prout, 1973b). However, the second of these results is rendered somewhat uncertain because of disorder in the crystals.

## 5. Discussion

The molecular dimensions of the component molecules in BP-DDQ leave no doubt that this molecular compound has a non-ionic ground state and thus resembles the molecular compounds of pyrene and perylene with DDQ (Ottenberg, Brandon \& Browne, 1964) but not those of DDQ with $N, N, N^{\prime}, N^{\prime}$-tetramethylphenylenediamine (Foster \& Thomson, 1963) or 2,5-diethoxy-pbenzoquinone (Hansen, 1968; Gorres \& Gurr, 1968). The electron affinity of DDQ is 3.13 eV (Chen \& Wentworth, 1975) while the vertical $\pi$-ionization potential of BP is 7.62 eV (Brogli \& Heilbronner, 1972).

The crystal structure of BP-DDQ shows a number of uncommon (though not entirely novel) features. First the periodicity along the stack axis is $\sim 14 \AA$, and the crystallographic repeat unit contains two formula units, related by the $c$ glide plane. This structure type with a double-unit periodicity along the stack axis is much less common than the single-unit type Icf. Tables 16 and 20 of Herbstein (1971)]. A similar type of stacking is found in anthracene-1,3,5-trinitrobenzene (Brown, Wallwork \& Wilson, 1964) and in $3 / 2$ pyrene-picryl bromide (Herbstein \& Kaftory, 1975).

The chains of DDQ molecules along [010] (Fig. 3a) and the $\mathrm{N} \cdots \mathrm{Cl}$ distance of $3.21 \AA$ suggest a weak donor-acceptor interaction (Bent, 1968) between CN and Cl groups, rather similar (also in details of geometry) to that found in 2,4,6-trichlorobenzonitrile (Carter \& Britton, 1972). Standard values of van der Waals radii $\mid \mathrm{N} 1 \cdot 5, \mathrm{Cl} 1.8 \AA$ (Pauling, 1960)| suggest that the shortening is only $0.09 \AA$, indicating a rather weak interaction. This could be an underestimate as Witt, Britton \& Mahon (1972) have suggested that $1.7 \AA$ may be
a more appropriate value for N . Stronger interactions, but with a linear geometry, have been found in CICN $[d(\mathrm{~N} \cdots \mathrm{Cl})=3.01 \AA($ Heiart \& Carpenter, 1956) $]$ and $\mathrm{Cl}-\mathrm{C} \equiv \mathrm{C}-\mathrm{CN} \mid d(\mathrm{~N} \cdots \mathrm{Cl})=2.97 \AA$ (Bjorvatten, 1968)].

The main feature of the overlap diagram (Fig. 4) is the positioning of the DDQ molecules on the phenanthrene regions of BP; a very similar overlap diagram has been found for perylene-fluoranil (Hanson, 1963), and similar features also appear in the overlap diagrams of perylene-tetracyanoquinodimethane (Tickle \& Prout, 1973a), and chrysene-TCNQ (Munnoch \& Wright, 1974). The predominance of shorter donor-acceptor distances along the stacks (Table 3) suggests a strong interaction in a direction perpendicular to the molecular planes. Indeed these atom-toatom distances are closer to the interplanar distances in the fluoranil molecular compounds of perylene (3.23 $\AA \AA ;$ Hanson, 1963), chrysene ( $3.23 \AA$; Munnoch \& Wright, 1975) and pyrene ( $3.28 \AA$; Bernstein \& Regev, 1977) than to those in the molecular compounds of chloranil [pyrene-chloranil $3.46 \AA$ (Prout \& Tickle, 1973)] or $p$-benzoquinone [pyrene- $p$-benzoquinone $3 \cdot 49 \AA$ (Bernstein et al., 1976)]. The specific interaction between carbonyl groups and aromatic rings proposed by Prout \& Wallwork (1966) is apparent in all these molecular compounds. However, superposition of the acceptor molecule over a phenanthrene portion of the donor does not occur in pyrene-chloranil, pyrene-pbenzoquinone or chrysene-fluoranil.

Perhaps the most interesting feature of the present results is the significant reduction in the deformation of the BP and, to a lesser extent, the DDQ molecules that occurs on their incorporation in the molecular compound. A somewhat similar effect has been reported in 13,3]paracyclophane-TCNE (Bernstein \& Trueblood, 1971); although there is no significant difference between the bond lengths and angles of [3,3]paracyclophane in its own crystals and those of the TCNE molecular compound, there is a small change in the distance between the parallel planes of the four unsubstituted $C$ atoms of the benzene rings of the paracyclophane molecule. This distance is 3.26 in the pure crystals and $3.20 \AA$ in the molecular compound. The change is about half as large as that in BP-DDQ. Unfortunately details are not available that will permit similar comparisons to be made for 1,12 -dimethylbenzolclphenanthrene and hexahelicene, where crystal structures have been reported both for the pure compounds (Hirshfeld, Sandler \& Schmidt, 1963; de Rango, Tsoucaris, Declercq, Germain \& Putzeys, 1973) and for their 4 -bromo-2,5,7-trinitrofluorenone molecular compounds (Ferguson, Mackay, Pollard \& Robertson, 1969).
The BP molecule is chiral and spontaneous resolution into enantiomers occurs on crystallization of benzolclphenanthrene (space group $P 2,2_{1} 2_{1}$; Herbstein \& Schmidt, 1954). In BP-DDQ each stack contains
both enantiomers in an alternating array, sandwiched between DDQ molecules (Fig. 2a). A similar situation occurs with hexahelicene, which is spontaneously resolved on crystallization as the pure compound (space group $P 22_{1} 2_{1}$; de Rango et al., 1973) but whose molecular compound with 4-bromo-2,5,7-trinitrofluorenone contains both enantiomers (space group $P \overline{1}$; Mackay, Robertson \& Sime, 1969).
