# Lobophytolide, a Cembranolide Diterpene 

By Rolf Karlsson<br>Department of Structural Chemistry, University of Stockholm, S-104 05 Stockholm, Sweden

(Received 10 September 1976; accepted 17 December 1976)
Lobophytolide, $\mathrm{C}_{20} \mathrm{H}_{28} \mathrm{O}_{3}, M_{r}=316 \cdot 4$, orthorhombic, $P 2_{1} 2_{1} 2_{1}$, with $a=22 \cdot 27$ (1), $b=13.837$ (7), $c=$ $6 \cdot 000$ (1) $\AA, Z=4, D_{m}=1 \cdot 14, D_{x}=1.135 \mathrm{~g} \mathrm{~cm}^{-3}$, m.p. $137^{\circ} \mathrm{C}$. Lobophytolide was isolated from the soft coral Lobophytum cristagalli. The 14 -membered carbon ring has two trans double bonds, one epoxide ring, and a quite flat five-membered lactone ring. The ester carbonyl is conjugated with an exocyclic methylene group. The absolute configuration was determined from ten enantiomer-sensitive Bijvoet differences.

## Introduction

Chemical and spectroscopic investigations of lobophytolide (LOB) (Fig. 1) were performed by Tursch, Braekman, Daloze, Herin \& Karlsson (1974). LOB crystallizes from a $n$-hexane-acetone mixture. The space group and refined cell constants were determined (and all data collection performed) with a Philips PW 1100 diffractometer. X-ray intensities from half

Fig. 1. The absolute configuration of lobophytolide.
the reciprocal sphere were collected (from a capillaryenclosed crystal) with graphite-monochromatized Cu $K \alpha$ radiation and the $\omega-2 \theta$ scan to a limit of $\theta<50^{\circ}$ set by the high temperature factor of the crystal. The data were reduced to 1138 independent intensities to which Lp factors were applied.

## Structure solution and refinement

Initial attempts to solve the structure by direct methods with $140 E$ values $>1.45$ were unsuccessful. A threeatom fragment later identified as $\mathrm{C}(1), \mathrm{C}(2)$ and $\mathrm{C}(3)$, of which $C(1)$ was the larger peak, was found in one of the $E$ maps. However, it was not possible to expand the three-atom structure by the tangent-recycling method (K arle, 1968). The phase problem was, however, solved when the $34 h k 0$ phases were determined prior to the other 106 phases. In the following $E$ map all nonhydrogen atoms appeared clearly.

The failure of the tangent formula to expand the three-atom structure is likely to be because of pseudocentrosymmetry; $\mathrm{C}(1), \mathrm{C}(17), \mathrm{O}(1)$ and $\mathrm{O}(2)$ have approximately the same Harker vectors, at the low resolution of the available data. The phases of the reflexions which were used for phase expansion [17,7,0

Fig. 2. A stereoscopic view of lobophytolide.
(90), 835 (292), 0,12,0 (180), 4,10,0 (0), 15,4,1 (12) and $193\left(172^{\circ}\right)$ ] become close to 0 or $180^{\circ}$ if the origin is shifted $\frac{1}{4}, 0, \frac{1}{4}$. The starting phases were generated by the convergence procedure (Germain, Main \& Woolfson, 1971) with $\Sigma_{\mathrm{k}}\left|E_{\mathrm{h}} E_{\mathrm{k}} E_{-\mathrm{h}-\mathrm{k}}\right|^{2}$ as the criterion

for the phase elimination. In order to break the centrosymmetry, reflexion $18,4,1$ was given the phase of $0^{\circ}$ and all phases were recycled to an average phase error of $24^{\circ}$ by minimizing

$$
P=\Sigma\left|E_{\mathrm{h}} E_{\mathrm{k}} E_{-\mathrm{h}-\mathrm{k}}\right|\left[1-\cos \left(\varphi_{\mathrm{h}}+\varphi_{\mathrm{k}}+\varphi_{-\mathrm{h}-\mathbf{k}}\right]^{2}\right.
$$

by the procedure described by Hauptman \& Weeks (1972). The common tangent formula which minimizes $\left.S=\Sigma\left|E_{\mathrm{h}} E_{\mathrm{k}} E_{-\mathrm{h}-\mathrm{k}}\right|\left\{\sin \left[\varphi_{\mathrm{h}}+\varphi_{\mathrm{k}}+\varphi_{-\mathrm{h}-\mathrm{k}}\right) / 2\right]\right\}^{2}$ is inadequate here since $S$ has a minimum while $P$ has a maximum for a centrosymmetric phase set (Lesk, 1976).

All the H atoms were found in a difference map. Least-squares refinement, with all atoms isotropic and all structure factors given equal weights, yielded $R=$ 0.09 .* The average coordinate shift in the last cycle was 0.09 e.s.d. The final difference map had no density exceeding $0.40 \mathrm{e}^{-3}$. Atomic scattering factors were taken from International Tables for X-ray Crystallography (1968). Final parameters are given in Table 1.

## Absolute configuration

Ten enantiomer-sensitive Bijvoet differences were measured (Table 2), by the diffractometer with $\mathrm{Cu} K \alpha$ radiation under conditions described by Karlsson (1976), from two crystals enclosed in capillaries. The dispersion parameters were taken from Cromer \& Liberman (1970). The signs of all the Bijvoet ratios, $2\left(I_{\mathrm{h}}-I_{-\mathrm{h}}\right) /\left(I_{\mathrm{h}}+I_{-\mathrm{h}}\right)$, measured for all equivalent reflexions from the larger crystal proved correct.

## Discussion

It can be seen from a stereoscopic view of LOB (Fig. 2) that the conformation of the 14 -membered ring is similar to that expected for a strain-free model of trans,trans-1,8-tetradecadiene, except for the part from $C(10)$ to $C(14)$, which is influenced by the epoxide and lactone rings. Bond distances and bond angles are given in Tables 3 and 4, torsion angles in Fig. 3. Com-

Fig. 3. Torsion angles $\left({ }^{\circ}\right)$ in lobophytolide.
parisons with other cembranolides are included in the discussion of sinulariolide (Karlsson, 1977).

I am indebted to Professor P. Kierkegaard and Professor B. Tursch (Brussels) for their kind interest. I thank Dr Braekman for the crystals and Dr D. F. Koenig for his correction of the English. The work has been supported by the Swedish Natural Science Research Council. I thank Dr Börje Lindberg for his suggestion to start with the $h k 0$ reflexions in the structure solution.
