# The Crystal and Molecular Structure of 2-Chloro-4-tert-butylthiacyclohexane Sulphoxide 

By Francis Robert<br>Laboratoire de Chimie des Métaux de Transition, Equipe de Recherche associée au CNRS no 608, 4 place Jussieu, 75230 Paris CEDEX 05, France

(Received 15 March 1977: accepted 7 May 1977)
$\mathrm{C}_{4} \mathrm{H}_{17} \mathrm{SOCl}$ is monoclinic, space group $P_{2} / c$, with $a=10 \cdot 987$ (3), $b=20.202$ (6), $c=10 \cdot 193$ (3) $\AA, \beta=$ $92.01(8)^{\circ}, ~ Z-8$. The structure was refined to a final $R$ of 0.048 for 2783 counter reflexions. The O atom is in the unusual equatorial position, and the thiacyclohexane ring is not distorted. The tert-butyl group is slightly twisted away from the staggered position.

## Introduction

The O atom of a thiacyclohexane sulphoxide prefers the axial to the equatorial position. It has been shown that the oxidation of 4 -substituted thianes (Johnson \& McCants, 1964, 1965) gives an equilibrium mixture. The compound present in the larger amount always has its O atom in the axial position. This is attributed to steric interaction between the O atom and the ring. The energy difference between the axial and the equatorial position was estimated to be about $-1.3 \mathrm{kcal} \mathrm{mol}^{-1}$. Further, electrophilic substitution on $\mathrm{C}_{\alpha}$ (Durst \& Fraser, 1970; Lett, Bory, Moreau \& Marquet, 1971; Nishihata \& Nishio, 1971; Bory, Lett, Moreau \& Marquet, 1972, 1973) was found to be very stereoselective. Sulphoxides with an equatorial $O$ atom were then prepared. Configurational assignment by systematic NMR studies of the products of methylation and halogenation of tert-butylthiacyclohexane sulphoxides (Lett, Bory, Moreau \& Marquet, 1973) showed anomalous chemical shifts which have been related to additional interactions introduced by the O atom in the
equatorial position. It was therefore of interest to apply X-ray analysis to this 4-tert-butylthiacyclohexane series. A preliminary account of 2 -chloro- 4 -tertbutylthiacyclohexane sulphoxide has appeared (Robert, 1974).

## Experimental section

The crystals are colourless needles. Cell constants were determined from oscillation and Weissenberg photographs. The systematic absences correspond to the space group $P 2_{1} / c$. Least-squares refinement of the Bragg angles of 64 reflexions led to $a=10.987$ (3), $b=$ $20 \cdot 202$ (6), $c=10 \cdot 193$ (3) $\AA ., \beta=92.01$ ( 8$)^{\circ}, V=$ $2267 \AA^{3}$. The density $\left(d_{o}=1.21, d_{c}=1.24 \mathrm{~g} \mathrm{~cm}^{-3}\right)$ is in agreement with two independent molecules per asymmetric unit (referred to as $A$ and $B$ ). Data were collected at room temperature with a $0.22 \times 0.25 \times$ 0.35 mm crystal mounted parallel to $\mathbf{c}$ on a Siemens AED diffractometer. 4700 reflexions were collected in the $\theta-2 \theta$ scan mode up to $\theta_{\text {max }}=66^{\circ}$ with $\mathrm{Cu} K a(\lambda=$

$1.5418 \AA$ ) Ni-filtered radiation. During data collection standard reflexions decreased by $20 \%$. This was attributed to sublimation, a common feature of sulphoxides at room temperature. After correction, 2783 reflexions with $I>3 \sigma(I)$, where $\sigma(I)$ is the standard deviation based on counting statistics, were considered as observed. Lorentz and polarization but no absorption corrections were applied ( $\mu=41.6$ $\mathrm{cm}^{-1}$ ). The scale and overall thermal parameters ( $B=$ $4.4 \AA^{2}$ ) were deduced from a Wilson plot.

## Structure solution

Cl and S coordinates were deduced from a Patterson function. A Fourier synthesis led to the coordinates of all non-hydrogen atoms. After full-matrix least-squares refinement with isotropic and then anisotropic thermal parameters, $R=\Sigma\left(| | F_{o}\left|-\left|F_{c}\right|\right|\right) / \Sigma\left|F_{o}\right|$ was $0 \cdot 110$,

somewhat high. A difference synthesis computed with all non-hydrogen atoms revealed a 3 e $\AA^{-3}$ peak at 1.95 $\AA$ from the non-substituted $\mathrm{C}_{\alpha}$ of $A$. This was interpreted as a statistical distribution of the Cl atom over both $\mathrm{C}_{\alpha}$ atoms. Refinement of the occupancy factor $x$ with equal isotropic thermal parameters for both atoms led to 0.82 and 0.18 for $x$ and $1-x$. These two atoms were then refined anisotropically to an $R$ of 0.079 . The Hamilton (1965) test showed this decrease to be significant. There is no statistical distribution on $B$. All H atoms were then located on a difference synthesis. Their coordinates were refined independently with isotropic thermal parameters equal to that of the C atom to which they are bound.

The final $R$ was 0.048 and $R_{w}$ was 0.047 with $R_{w}=$ $\left[\Sigma w\left(\left|F_{0}\right|-\left|F_{c}\right|\right)^{2} / \Sigma w F_{t}^{2}\right]^{1 / 2}$ (here $w=1 \cdot 0$ ). The atomic coordinates are listed in Tables 1 and 2.*

[^0]

Fig. 1. Atomic numbering and bond distances $(\AA)$. The estimated standard deviations are less than $0.009 \AA$ for $\mathrm{C}-\mathrm{C}, \mathrm{C} \cdot \mathrm{Cl}, \mathrm{C}-\mathrm{S}$, S-- O bonds and $0.06 \AA$ for $\mathrm{C}-\mathrm{H}$ bonds.

All calculations were performed on an IBM 370-168 computer with local versions of ORFLS (Busing, Martin \& Levy, 1962) for least-squares refinement, GEST (De Rango, Tsoucaris, Zelwer \& Baudour, 1964) for Fourier syntheses and NRC programs (Ahmed, Hall, Pippy \& Huber, 1966) for geometrical calculations. Scattering factors were taken from International Tables for X-ray Crystallography (1962) $[F(000)=896]$. The anomalous dispersion of the Cl atom was ignored.

## Structure description

Atomic numbering and interatomic distances are shown in Fig. 1. Bond angles are listed in Table 3. The geometrical parameters will be compared with those of 4-tert-butylcyclohexane |force-field calculations (Altona \& Sundaralingam, 1970, hereinafter AS, 1970)| and to different substituted 4-tert-butylcyclohexane Xray structure investigations, e.g. cis-4-tert-butylcyclo-hexane-1-carboxylic acid (referred to as BCA) (van Koningsveld, 1972) and 2b-seq-cis-1-phenyl-4-tertbutylcyclohexanecarboxylic acid (referred to as

PBCA) (Mallissard, Sicsic, Welvart, Chiaroni, Riche \& Pascard-Billy, 1974).

## Thiacyclohexane ring

The ring is anchored in the chair conformation by the tert-butyl group in the equatorial position. Planes $P 1$ defined by $\mathrm{C}(2), \mathrm{C}(3), \mathrm{C}(5), \mathrm{C}(6)$ and $P 2$ defined by $C^{\prime}(2), C^{\prime}(3), C^{\prime}(5), C^{\prime}(6)$ (Table 4) show that the mean distances of these atoms to their planes ( $d_{\text {mean }}=0.009$ $\AA$ ) is about twice the corresponding standard deviation (e.s.d.mean $=0.005 \AA$ ). Thus the expected distortion of the ring consistent with the twist of the tert-butyl group cannot be firmly established.
$C(4)$ and $C^{\prime}(4)$ are respectively +0.68 and $+0.69 \AA$ out of $P 1$ and $P 2$ while $S$ and $S^{\prime}$ are -0.98 and -0.96 $\AA$ out of the same planes. This can be related to the $C(3)-C(4)-C(5)$ angles (110.6 and $109 \cdot 1^{\circ}$ ): the angles reported for BCA and PBCA are respectively 107.9 and $108.4^{\circ}$. The $\mathrm{C}(2)-\mathrm{S}-\mathrm{C}(6)$ angles ( 95.6 and $96 \cdot 1^{\circ}$ ) are similar to those chosen in sulphoxide conformational analysis $\left(95.8^{\circ}\right)$ by Allinger, Hirsch, Miller \& Tyminski (1969) and to the values tabulated by Chu (1975) for three-coordinate S in thioxanthene derivatives $\left(98.58^{\circ}\right)$. The mean $\mathrm{C}-\mathrm{C}$ length of 1.527

Table 3. Bond angles $\left({ }^{\circ}\right)$
The e.s.d.'s in parentheses refer to the last decimal place; those for the hydrogen bond angles range from $2.5^{\circ}$ for $\mathrm{C}-\mathrm{C}-\mathrm{H}$ to $5.0^{\circ}$ for $\mathrm{H}-\mathrm{C}-\mathrm{H}$.

Fig. 2. Ring torsion angles $\left({ }^{\circ}\right)$ for both molecules.
$\AA$ is in agreement with that of the semi-empirical forcefield model of AS (1970) ( $1.533 \AA$ ) and those reported for cyclohexane derivatives; $1.529 \AA$ has been found for trans-1,4-aminomethylcyclohexanecarboxylic acid (Groth, 1968). Fig. 2 shows the ring torsion angles for $A$ and $B$. The average value $\left(61 \cdot 2^{\circ}\right)$ is far above that found for cyclohexane $\left(54.5^{\circ}\right)$ by Bucourt \& Hainaut (1965) but is in agreement with the AS (1970) prediction for heterocyclic compounds, which allows for a decreased $\mathrm{C}-\mathrm{S}-\mathrm{C}$ angle.

A

B

Fig. 3. Newman projections through the $\mathrm{C}(4)-\mathrm{C}(7)$ bond.

## Sulphoxide group

The $O$ atom, as predicted, is bound in the energetically unfavourable equatorial position. The S-O distances ( 1.490 in $A$ and $1.489 \AA$ in $B$ ) are slightly longer than those found in 1,4-dithiane 1,4dioxide ( $\alpha$ form) (Shearer, 1959) but agree with those reported by Chu (1975) for thioxanthene derivatives ( $1.497 \AA$ ), and by Palmer \& Lee (1966), De la Camp \& Hope (1970) and Hine (1962) for other cyclic sulphoxides.

## tert-Butyl group

The tert-butyl group is twisted away from the staggered position (mean value of twist $8^{\circ}$ for $A$ and $6^{\circ}$ for $B$ ). These values agree with $8^{\circ}$ for BCA and $6^{\circ}$ for PBCA, but are far from the calculated value $\left(17^{\circ}\right)$ of AS (1970). Fig. 3 is the Newman projection through $\mathrm{C}(4)-\mathrm{C}(7)$. The mean $\mathrm{C}(4)-\mathrm{C}(7)$ length is less ( 1.546 $\AA$ ) than other values ( 1.561 for PBCA and $1.550 \AA$ for BCA). AS (1970) calculated $1.570 \AA$ but suggested that the probable true value would be $1.564 \AA$.

The $1.777 \AA \mathrm{C}-\mathrm{Cl}$ distance of $B$ agrees with 1.767 $\AA$ (Sutton, 1965). On the other hand, both $\mathrm{C}-\mathrm{Cl}$ distances in $A$ are too long ( 1.841 and $1.947 \AA$ ). This may be due to the disorder. A $1.92 \AA \mathrm{C}-\mathrm{Cl}$ distance has been reported in the disordered structure of 3 -chloro-3-iodopropyltrimethylammonium iodide (Mallard, Vaughan \& Hamor, 1974). The packing is governed by van der Waals contacts; no particular short distances were found.

The author thanks Dr C. Stora for her interest in the work, $\operatorname{Dr}$ A. Marquet for suggesting this study and supplying the crystals, and the Crystallographic Laboratory of the University of Bordeaux for data collection.

# The Crystal and Molecular Structure of 2-Chloro-4-tert-butyl-6-methylthiacyclohexane Sulphoxide 

By Francis Robert and Sylvie Gauchotte<br>Laboratoire de Chimie des Métaux de Transition, Equipe de Recherche associée au CNRS n० 608, 4 place Jussieu, 75230 Paris CEDEX 05, France

(Received 15 March 1977; accepted 7 May 1977)
$\mathrm{C}_{10} \mathrm{H}_{19} \mathrm{SOCl}$ is orthorhombic, space group Pbcn , with $a=20.124$ (5), $b=12.921$ (3), $c=9.238$ (2) $\AA . Z=$ 8. The structure was refined to a final $R$ of 0.078 for 1274 counter reflexions. The O atom is in the axial position. The weak ring distortion is related to the twist of the tert-butyl group.

## Introduction

Having solved the structure of 2-chloro-4-tert-butylthiacyclohexane sulphoxide (CTTH, Robert, 1977) we report the structure of 2 -chloro-4-tert-butyl-6-methylthiacyclohexane sulphoxide. Our goal is to obtain information on conformational differences, if any, of the thiacyclohexane ring. Since the O atom in CTTH is equatorial and because NMR shows an axial $O$ atom in the title compound it is interesting to look for distortion differences in the ring.

During this work we will refer to force-field calculations of 4-tert-butylcyclohexane (Altona \& Sundaralingam, 1970, hereinafter AS, 1970) and to two

X-ray investigations: cis-4-tert-butylcyclohexane-1carboxylic acid (van Koningsveld, 1972) and $2 b$ seq. cis-1-phenyl-4-tert-butylcyclohexanecarboxylic acid (Mallissard, Sicsic, Welvart, Chiaroni, Riche \& Pascard-Billy, 1974) referred to respectively as BCA and PBCA.

## Experimental

The description by Bory, Lett, Moreau \& Marquet (1973) of halogenation of sulphoxides shows the high stereoselectivity of these reactions. This stereoselectivity has been used to isolate the title compound.
