# The Crystal Structure of Magnesium Dimolybdate 

By K. Stadnicka<br>Institute of Chemistry, Jagiellonian University, ul. Krupnicza 41, 30-060 Kraków, Poland

and J. Haber and R. Kozlowski<br>Research Laboratories of Catalysis and Surface Chemistry, Polish Academy of Sciences, ul. Niezapominajek, 30-239 Kraków, Poland

(Received 22 November 1976; accepted 25 June 1977)
The structure of magnesium dimolybdate, $\mathrm{MgMo}_{2} \mathrm{O}_{7}$, monoclinic with space group $P 2_{1} / c$ and $a=8.111$ (2), $b=5.700$ (1), $c=15.002$ (3) $\AA, \beta=115.26(2)^{\circ}, Z=4$, was determined by the heavy-atom method and refined by full-matrix least squares to an $R$ of 0.095 for 2558 counter reflexions. The $\mathrm{Mo}_{2} \mathrm{O}_{7}^{2-}$ pyro-anion consists of two corner-sharing $\mathrm{MoO}_{4}$ tetrahedra, which are twisted from the ideal eclipsed configuration by an average of $12 \cdot 3^{\circ} . \mathrm{Mo}_{2} \mathrm{O}_{7}$ groups form anionic sheets parallel to the (100) plane. $\mathrm{Mg}^{2+}$ ions are situated between the anionic sheets in a distorted-octahedral environment of O atoms. $\mathrm{MgO}_{6}$ octahedra share one edge forming $\mathrm{Mg}_{2} \mathrm{O}_{10}$ units.

## Introduction

The phase equilibrium diagram for the system of $\mathrm{MgMoO}_{4}-\mathrm{MoO}_{3}$ has been investigated (Zhukovskii, Tkachenko \& Rakova, 1970) and only one compound, of the composition $\mathrm{Mg}_{2} \mathrm{Mo}_{3} \mathrm{O}_{11}$, was found. Our preliminary studies showed that two compounds, of chemical formulae $\mathrm{Mg}_{2} \mathrm{Mo}_{3} \mathrm{O}_{11}$ and $\mathrm{MgMo}_{2} \mathrm{O}_{7}$, exist in this system.

Attempts to obtain single crystals of the $\mathrm{MgMo}_{2} \mathrm{O}_{7}$ compound proved successful and the crystal structure investigation was undertaken.

## Experimental

Single crystals of $\mathrm{MgMo}_{2} \mathrm{O}_{7}$ were grown from a melt of $0.15 \mathrm{~mol} \% \mathrm{MgO}$ and $0.85 \mathrm{~mol} \% \mathrm{MoO}_{3}$, ${ }^{*}$ making use of the sublimation of $\mathrm{MoO}_{3}$ at higher temperatures. Crystallization was performed in an open quartz tube by heating the mixture at $800^{\circ} \mathrm{C}$ for 48 h . After cooling, a large number of pale-pink crystals of poorly defined morphology were obtained. The $\mathrm{Mg} / \mathrm{Mo}$ atomic ratio in the crystals, as determined by atomic absorption spectroscopy, was 1:2. Laue photographs showed well-formed reflexions and Weissenberg photographs indicated monoclinic symmetry with space group $P 2_{1} / c$ (systematic absences: $0 k 0$ for $k$ odd, $h 0 l$ for $l$ odd). Cell parameters were obtained by leastsquares refinement from the setting angles of the 15 strong reflexions used in the auto-indexing procedure. The density of the investigated crystals was determined by a pycnometric method in carbon tetrachloride.

[^0]
## Crystal data

$\mathrm{MgMo}_{2} \mathrm{O}_{7}$, monoclinic, $M_{r}=328 \cdot 2$, space group $P 2_{1} / c, a=8.111$ (2), $b=5.700$ (1), $c=15.002$ (3) $\AA$, $\beta=115.26(2)^{\circ}, V=627.3 \AA^{3}, Z=4, D_{x}=3.475$, $D_{m}=3.22 \mathrm{~g} \mathrm{~cm}^{-3}, F(000)=608, \lambda($ Мо $K(\mathrm{r})=$ $0.71069 \AA, \mu\left(\right.$ Mo $K(r)=42.58 \mathrm{~cm}^{-1}$.

For a crystal ground to the approximate shape of an ellipsoid with dimensions $0.27 \times 0.21 \times 0.21 \mathrm{~mm}$, intensity data were collected on a CAD-4 single-crystal diffractometer (Enraf-Nonius) using graphite-monochromated Mo $K_{\text {I }}$ radiation.* Measurements were taken in the range of theta from 1 to $35^{\circ}$ with the $\theta-2 \theta$ scan mode and a scan width of $0.65^{\circ}+0.40^{\circ} \tan \theta$. The intensities were corrected for background, Lorentz and polarization effects and the absorption correction for an ellipsoid was applied with Buda's (1977) program. No correction was made for extinction. Scaling of intensities was achieved with a reference reflexion recorded after each group of 47 measurements. The fluctuation in the intensity of the standard reflexion was random and less than $5 \%$. Out of 2628 independent reflexions measured, 21 were found to have intensities less than zero and 49 were not significantly above background [ $I<1.5 \sigma(I)$ ]. Therefore, 2558 intensities were used in further calculations.

## Structure solution and refinement

The coordinates of the two Mo atoms in the asymmetric unit were determined from a three-dimensional

[^1]Table 1. Positional parameters $\left(\times 10^{4}\right)$ with estimated standard deviations in parentheses

|  | $x$ | $y$ | $z$ |
| :--- | :---: | :--- | :--- |
| Mo(1) | $7474 \cdot 1(5)$ | $6259 \cdot 9(4)$ | $3638 \cdot 5(3)$ |
| $\mathrm{Mo}(2)$ | $12073.7(5)$ | $6340 \cdot 2(6)$ | $3712 \cdot 9(3)$ |
| Mg | $5155(2)$ | $1265(2)$ | $4103(1)$ |
| $\mathrm{O}(1)$ | $6955(5)$ | $3913(6)$ | $4220(3)$ |

| $\mathrm{O}(5)$ | $13208(5)$ | $3688(5)$ | $4021(3)$ |
| $\mathrm{O}(6)$ | $13619(5)$ | $8646(5)$ | $4335(3)$ |
| $\mathrm{O}(7)$ | $11452(6)$ | $6777(9)$ | $2486(3)$ |

Patterson map. After refinement of the Mo parameters ( $R=0.23$ ), a difference map revealed all the missing atoms. The structure was refined by the full-matrix least-squares method on the basis of 2558 observed reflexions. All calculations were performed with the SHELX program system (Sheldrick, 1975) in which the following weighting scheme was used: $w=k\left[\sigma^{2}\left(F_{o}\right)\right.$ $\left.+|g| F_{o}^{2}\right]^{-1}$.

Values of $k$ and $g$ were refined to 1 and 0.0857 respectively. The atomic scattering factors of Mo and Mg were taken from International Tables for X-ray Crystallography (1974) and $\Delta f^{\prime}$ and $\Delta f^{\prime \prime}$ corrections for anomalous dispersion were from Cromer (1965). The refinement with anisotropic temperature factors for all atoms was stopped when the shifts of the parameters were less than $0 \cdot 1$ of their estimated standard deviations for all atoms, except those for $U_{22}$ of $\mathrm{Mo}(1)$ and $\operatorname{Mo}(2)$ which, however, did not exceed 0.5 of their e.s.d.'s.

Despite the application of a damping factor, better convergence was difficult to obtain because of correlations between the anisotropic temperature factors of both Mo atoms. The last difference Fourier synthesis revealed several, randomly distributed peaks not larger than 2 e $\AA^{-3}$. The final discrepancy indices for all reflexions were as follows: $R=0.095, R_{w}=0.102$ and $R_{G}=0.156$ where $R=\Sigma| | F_{o}\left|-\left|F_{c} \||/ \Sigma| F_{o}\right|, R_{w}=\right.$ $\Sigma w^{1 / 2}| | F_{o}\left|-\left|F_{c}\right| / \Sigma w^{1 / 2}\right| F_{o} \mid$ and $R_{G}=\left[\Sigma w\left(\left|F_{o}\right|-\right.\right.$ $\left.\left|F_{c}\right|\right)^{2} /\left.\sum w F_{o}^{2}\right|^{1 / 2}$. There are about 80 strong reflexions observed (i.e. $3 \%$ ) with $\left|F_{o}\right|$ considerably lower than $\left|F_{c}\right|$. These differences, resulting in the relatively high $R$ factor, can be attributed to the effect of extinction. The final positional parameters are presented in Table 1.*

## Description of the structure

The bond lengths and angles found in the structure of the title compound are given in Table 2. Mo atoms are

[^2]surrounded by four O atoms, arranged in a slightly distorted tetrahedron. The $\mathrm{MoO}_{4}$ tetrahedra share corners forming discrete $\mathrm{Mo}_{2} \mathrm{O}_{7}^{2-}$ ions (Fig. la) with a $\mathrm{Mo}(1)-\mathrm{O}(4)-\mathrm{Mo}(2)$ angle of 160.7 (3) ${ }^{\circ}$. The unshared O atoms are twisted somewhat from the ideal eclipsed configuration of mm symmetry (Fig. 1b). According to Panagiotopoulos \& Brown (1973) the

Fig. 1. (a) View of the dimolybdate ion $\mathrm{Mo}_{2} \mathrm{O}_{7}^{2-}$ projected on the Mo(1), $\mathrm{O}(4) . \mathrm{Mo}(2)$ plane; (b) projection down the $\mathrm{Mo}(1)-$ $\mathrm{Mo}(2)$ direction.
relative orientation of $\mathrm{MoO}_{4}$ groups in pyro-anions can be described by two torsion angles, $\alpha_{1}$ and $\alpha_{2}$. They are defined as the rotation angles of the terminal O atoms about the $\mathrm{Mo}(1)-\mathrm{Mo}(2)$ axis out of the plane of the bridging O and both Mo atoms. The $\alpha_{1}, \alpha_{2}$ angles are positive when the terminal O is rotated clockwise from this plane as viewed from the bridging O atom. The mean value of $\alpha_{1}$ is $+5 \cdot 3^{\circ}$, that of $\alpha_{2}$ is $+7 \cdot 0^{\circ}$ and the average twist angle of $\alpha_{1}+\alpha_{2}$ equals $12.3^{\circ}$ in the structure of $\mathrm{MgMo}_{2} \mathrm{O}_{7}$.

The bridging $\mathrm{Mo}(1)-\mathrm{O}(4)$ and $\mathrm{Mo}(2)-\mathrm{O}(4)$ distances are 1.857 (4) and 1.881 (4) $\AA$ respectively. The $\mathrm{Mo}(2)-\mathrm{O}(7)$ distance of 1.707 (4) $\AA$ is the shortest $\mathrm{Mo}-\mathrm{O}$ bond length in $\mathrm{MgMo}_{2} \mathrm{O}_{7} . \mathrm{O}(7)$ forms contacts

Fig. 2. $\mathrm{MgMo}_{2} \mathrm{O}$, structure projected down $\mathbf{b}$.

Fig. 3. Conformation types of the $X_{2} \mathrm{O}_{7}$ group from Panagiotopoulos \& Brown (1973): (a) staggered, (b) and (c) eclipsed.
only with $O\left(4^{\text {iii }}\right), O\left(2^{\text {iii }}\right)$ and $O\left(7^{\text {iii) }}\right)$ oxygen atoms. The Mo-O bond lengths involving $\mathrm{O}(1), \mathrm{O}(2)$ and $\mathrm{O}(5)$, which are coordinated to one Mg atom, vary from 1.720 (3) to 1.744 (3) $\AA$, while in the case of $\mathrm{O}(6)$, coordinated to two Mg atoms, the $\mathrm{Mo}(2)-\mathrm{O}(6)$ distance is 1.781 (3) $\AA$. The mean Mo-O bond length of 1.77 (2) $\AA$ agrees very well with that of $1.77 \AA$ quoted by Schröder (1975) as the characteristic average $\mathrm{Mo}-\mathrm{O}$ distance in $\mathrm{MoO}_{4}$ tetrahedra. The mean interbond $\mathrm{O}-\mathrm{Mo}-\mathrm{O}$ angle in $\mathrm{Mo}_{2} \mathrm{O}_{7}$ of 109.4 (7) ${ }^{\circ}$ is in agreement with the ideal value of the tetrahedral angle. The thermal vibration of the bridging O atom is not larger than those of the terminal atoms. The direction defined by the $\operatorname{Mo}(1)$ and $\operatorname{Mo}(2)$ atoms of the same pyro-anion is almost parallel to a. The packing of the dimolybdate groups in the unit cell is shown in Fig. 2.
$\mathrm{Mo}_{2} \mathrm{O}_{7}^{2-}$ ions form anionic sheets parallel to the (100) plane. The Mg atoms are situated between anionic sheets so that each Mg atom is coordinated by six O atoms arranged in a distorted octahedron. The mean $\mathrm{Mg}-\mathrm{O}$ distance is 2.06 (1) $\AA$ and the average $\mathrm{O}-\mathrm{Mg}-\mathrm{O}$ interbond angle $90(1)^{\circ} . \mathrm{MgO}_{6}$ octahedra share one edge forming $\mathrm{Mg}_{2} \mathrm{O}_{10}$ units in which the distance $\mathrm{Mg}-\mathrm{Mg}^{\mathrm{i}}$ is $3 \cdot 156 \AA$.

## Discussion

So far, dimolybdate crystal structures of $\mathrm{Na}^{+}$ (Seleborg, 1967), $\mathrm{K}^{+}$(Maganill \& Klevtsova, 1971), $\mathrm{NH}_{4}^{+}$(Knöpnadel, Hartl, Hunnius \& Fuchs, 1974) and $\mathrm{Ag}^{+}$(Gatehouse, 1974; Gatehouse \& Leverett, 1976) have been determined. None contain discrete $\mathrm{Mo}_{2} \mathrm{O}_{7}^{2-}$ ions, their structures being composed of octahedral ( $\mathrm{Ag}^{+}$salt), or octahedral-tetrahedral $\left(\mathrm{Na}^{+}, \mathrm{K}^{+}, \mathrm{NH}_{4}^{+}\right.$ salts) infinite chains. Nor have isolated $\mathrm{W}_{2} \mathrm{O}_{7}^{2-}$ anions been found in the structures of $\mathrm{Na}^{+}$(Okada, Morikawa, Marumo \& Iwai, 1975a) and $\mathrm{Li}^{+}$(Okada et al., 1975b) ditungstates. $\mathrm{MgMo}_{2} \mathrm{O}_{7}$ is, thus, the first dimolybdate which has been found to belong to a large class of compounds containing isolated $X_{2} \mathrm{O}_{7}$ groups composed of $\mathrm{XO}_{4}$ tetrahedra sharing corners. This class of compounds can be divided into three groups differing with respect to the relative conformation of the $X_{2} \mathrm{O}_{7}$ group. These idealized conformations are illustrated in Fig. 3 (Panagiotopoulos \& Brown, 1973). In part (a) of
this figure, the unshared O atoms are in the staggered conformation, whereas (b) and (c) represent two possible eclipsed forms. Further classification of the discussed group of compounds is based on the value of the $X-\mathrm{O}-X$ interbond angle which, in theory, can vary from 102 to $180^{\circ}$ (Clark, 1972). Usually it falls within the range $110-155^{\circ}$. The $\mathrm{Mo}_{2} \mathrm{O}_{7}^{2-}$ ion described in the present paper is close to the configuration in Fig. 3(c) with a twist angle of $12^{\circ}$ and Mo-O-Mo angle of $161^{\circ}$.

# Solid-State Phase Transition in Carbon Tetrabromide. II. The Crystal Structure of Phase I 

By M. More, J. Lefebvre and R. Fouret<br>Laboratoire de Physique des Solides, Equipe de Dynamique des Cristaux Moléculaires associée au CNRS ( $n^{\circ} 465$ ), Université de Lille I, BP 36, 59650 Villeneuve d'Ascq, France

(Received 24 May 1977; accepted 25 June 1977)

#### Abstract

Phase I of $\mathrm{CBr}_{4}$ (above $47^{\circ} \mathrm{C}$ ) is cubic, space group $\mathrm{Fm} 3 m$, with $a=8.82 \AA, Z=4$. The molecules are orientationally disordered and the structure is described by the use of symmetry-adapted functions. The orientational probability is discussed in terms of these functions.

## Introduction

The high-temperature phase of $\mathrm{CBr}_{4}$ (above $47^{\circ} \mathrm{C}$ ) is 'plastic' with the molecules orientationally disordered.

As a first approximation, the disorder can be interpreted by assuming that the molecule occupies at random any one of $N$ distinguishable orientations, the mean symmetry being cubic (Frankel model). If one neglects correlations, thermal entropy, etc., the transition entropy is approximately $\Delta S_{t}=R \ln N$.

In $\mathrm{CBr}_{4}, \Delta S_{t}=4.98 \mathrm{cal} \mathrm{K} \mathrm{K}^{-1} \mathrm{~mol}^{-1}$ (Marshall, Staveley \& Hart, 1956; Hildebrand \& Scott, 1950).

Guthrie \& McCullough (1961) suppose that the orientational disorder corresponds to the 10 distinguishable orientations of the combined $T_{d}$ and $C_{3 v}$ symmetry ( $R \ln 10=4.58 \mathrm{cal} \mathrm{K}^{-1} \mathrm{~mol}^{-1}$ ).

In a previous paper (More, Baert \& Lefebvre, 1977), we reported that one can expect six different molecular orientations corresponding to $D_{2 d}$ local symmetry.

However, a classical refinement of the high-temperature-phase diffraction data, based on a Frankel model with six equilibrium positions, has failed.

In this paper, we report the structure refined by the use of symmetry-adapted functions. This method takes

[^0]:    * Both are commercial products.

[^1]:    *The intensity measurement was carried out in the X-ray Division of the Regional Laboratory of Physicochemical Analysis and Structure Research, Kraków.

[^2]:    * Lists of structure factors and anisotropic thermal parameters have been deposited with the British Library Lending Division as Supplementary Publication No. SUP 32845 ( 18 pp .). Copies may be obtained through The Executive Secretary, International Union of Crystallography, 13 White Friars, Chester CHI 1NZ, England.
