# The Structure of the Orange Complex $\left[\mathrm{Ru}\left(\mathbf{S}_{2} \mathbf{C H}\right)\left(\mathrm{PMe}_{2} \mathrm{Ph}_{4}\right] \mathrm{PF}_{6}\right.$ : Dithioformato[tetrakis(dimethylphenylphosphine)]ruthenium(II) Hexafluorophosphate 

By Michael Laing<br>Chemistry Department, University of Natal, Durban 4001, South Africa

(Received 2 January 1978; accepted 4 February 1978)
$\left[\mathrm{Ru}\left(\mathrm{S}_{2} \mathrm{CH}\right)\left(\mathrm{PMe}_{2} \mathrm{Ph}_{4}\right] \mathrm{PF}_{6}\right.$ is orthorhombic, $\mathrm{Pb} c a, a=13.550(10), b=19.480(15), c=28.880(25) \AA, Z$ $=8$. $R=0.0816$ for 2649 counter data; $R u$, two $S$ and five $P$ atoms anisotropic. The coordination about Ru is distorted octahedral. Bond lengths are: $\mathrm{Ru}-\mathrm{S} 2.43,2.44 ; \mathrm{Ru}-\mathrm{P}(\mathrm{ax}) 2.42,2.43 ; \mathrm{Ru}-\mathrm{P}(\mathrm{eq}) 2.34,2.36$; $\mathrm{S}-\mathrm{C} 1.65,1.68 \AA$. Bond angles are: $\mathrm{P}(\mathrm{eq})-\mathrm{Ru}-\mathrm{P}(\mathrm{eq}) 100$; $\mathrm{P}(\mathrm{ax})-\mathrm{Ru}-\mathrm{P}(\mathrm{ax}) 167$; $\mathrm{S}-\mathrm{Ru}-\mathrm{S} 70 ; \mathrm{P}(\mathrm{eq})-$ $\mathrm{Ru}-\mathrm{P}(\mathrm{ax}) 93,92,91,99 ; \mathrm{S}-\mathrm{Ru}-\mathrm{P}(\mathrm{ax}) 87,88,83,84$; trans $\mathrm{S}-\mathrm{Ru}-\mathrm{P}(\mathrm{eq}) 163,167^{\circ}$. The distortions from regularity about the Ru atom are caused by close contacts between methyl and phenyl groups in each set of facial phosphine ligands, and between phenyl rings on the axial phosphines and one $S$ atom. Because the $x$ coordinate of the Ru atom is close to $0 \cdot 25$, one $\mathrm{P}-\mathrm{Ru}-\mathrm{S}$ vector is nearly collinear with $b$, and the $\mathrm{P}-\mathrm{Ru}-\mathrm{P}$ and second $\mathrm{P}-\mathrm{Ru}-\mathrm{S}$ vector lie in the $x z$ plane at about $45^{\circ}$ to the $y z$ plane, the solution of the structure by the Patterson method is not straightforward. A brief discussion is given of the techniques used to obtain the coordinates of the heavy atoms of the cation.

## Introduction

Reaction of $\left[\mathrm{RuH}\left(\mathrm{PMe}_{2} \mathrm{Ph}_{5}\right] \mathrm{PF}_{6}\right.$ with $\mathrm{CS}_{2}$ in cold deoxygenated methanol (Ashworth, 1977) yields the orange dithioformato complex $\left[\mathrm{Ru}\left(\mathrm{S}_{2} \mathrm{CH}\right)\right.$ $\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{4} \mathrm{PF} \mathrm{P}_{6}$ (I) which rearranges in boiling methanol to a purple isomer $\left[\mathrm{Ru}\left\{\mathrm{S}_{2} \mathrm{C}(\mathrm{H}) \mathrm{PMe}_{2} \mathrm{Ph}\right\}\right.$ $\left(\mathrm{PMe}_{2} \mathrm{Ph}_{3}{ }_{3} \mathrm{PF}_{6}\right.$ (II) (Ashworth, Singleton \& Laing, 1976a). This unusual rearrangement from a $\mathrm{Ru}^{\mathrm{II}}$ complex of coordination number 6 and electron count 18 to one of coordination number 5 and electron count 16 (Sidgwick, 1927; Tolman, 1972) was evidently favoured by a reduction of the intramolecular interligand strains (Ashworth, Nolte, Singleton \& Laing, 1977). The structure of the orange dithioformato complex has been determined to obtain detailed information about the non-bonded contacts between the dimethylphenylphosphine ligands.

(II)

## Experimental

Crystals were supplied by Drs T. V. Ashworth and E. Singleton. Cell dimensions (Table 1) were obtained by least squares from $2 \theta, \chi$ and $\varphi$ angles for 25 reflexions measured on a Philips four-circle diffractometer. Intensities were measured for a crystal $0.2 \times 0.2$
$\times 0.2 \mathrm{~mm}$ with graphite-monochromated Mo $K \alpha$ radiation ( $\lambda=0.7107 \AA$ ) for $\theta$ between 3 and $20^{\circ}$. The $\omega-2 \theta$ scan technique was used; the scan width was $0.7^{\circ}$, the scan time was 23.3 s , and the background was counted for 23.3 s for each reflexion. Three reflexions were used as standards and remeasured after every 60 reflexions; no decomposition was observed. Of the 3984 reflexions measured (including spacegroup extinctions) 2649 were classed as observed, $I$ > $1.65 \sigma(I)$. Only Lorentz-polarization corrections were applied; $\mu(\mathrm{Mo} K c)=7.7 \mathrm{~cm}^{-1}$.

A Patterson map had a pattern of large peaks close to the origin which showed that the cation was octahedral with one $L-\mathrm{Ru}-L$ vector lying nearly parallel to $b$, and that the other two $L-\mathrm{Ru}-L$ vectors lay in the $x z$ plane, each making an angle close to $45^{\circ}$ with the $y z$ plane. The pattern of peaks on the Harker sections and lines confirmed these deductions and gave the coordinates of the Ru atom. There was no way of differentiating the P from the S atoms. As a check, the structure was solved independently by direct methods. The intensity statistics were: $\left.\langle | E\left\rangle 0.72,\langle | E^{2}-1\right|\right\rangle$ 1.07, $\langle | E^{2}| \rangle 0.94 ; E$ 's $>3.00 .63 \%,>2.04 .57 \%$, $>1.020 .9 \%$; a distribution typical of slight hypersymmetry. The 305 largest $E$ 's were used in the

Table 1. Crystal data

program SAYRE (Long, 1965) with NBACK $=1$. The origin-fixing reflexions were chosen by hand, but the program was allowed to choose four variables (Table 2). The correct solution had the highest consistency index $(0.9898)$ and was reached in the smallest number of cycles (5). 150 signs were positive, 155 were negative, and the $E$ map clearly showed both the $\mathrm{RuP}_{4} \mathrm{~S}_{2}$ group and the P of the $\mathrm{PF}_{6}^{-}$ion. It was still impossible to differentiate between the P and S atoms in the cation.

A Fourier map, phased on Ru and seven P atoms, yielded coordinates for most of the C atoms, and the connectivity of the peaks allowed the S atoms to be identified. When all the atoms had been correctly placed, the structure was refined by block-diagonal least squares, first isotropically, then with the Ru , five P and two S atoms anisotropic. The final $R$ was 0.0816

Table 2. Reflexions used as the starting set in the program SAYRE

| $h k l$ | $E$ | Correct solution | Origin definers |
| :---: | :---: | :---: | :---: |
| 183 | 3.80 | + |  |
| 1216 | $3 \cdot 69$ | + |  |

| 289 | 3.75 |  |  |
| 387 | $4 \cdot 12$ | + |  |

for 2649 observed data.* [This value of $R$ is slightly higher than is usual for diffractometer data and is caused by a small systematic error that cannot be corrected for. This error arises from the combination of the long cell edges ( $b=19.48, c=28.88 \AA$ ), the short wavelength of the radiation $(0.7107 \AA)$ and the configuration of the diffractometer, which causes a small but unavoidable overlap of reflexions resulting in incorrect values for the background measurements in the vicinity of strong reflexions. The errors in the intensities probably cause the $\beta_{i j}$ 's of the heavy atoms to be incorrect and their standard deviations should best be doubled.] Weighting was proportional to $1 / \sigma(F)$; scattering factors for neutral atoms were used; that of Ru was corrected for anomalous dispersion (International Tables for X-ray Crystallography, 1962). Final positional and isotropic thermal parameters are given in Table 3, bond lengths in Table 4, bond angles in Table 5 and non-bonded contacts in Table 6.

## Discussion

The coordination about the Ru atom in the cation is distorted octahedral. The four phosphine ligands are arranged as two pairs, one trans and one cis, with the

bidentate dithioformate group completing the octahedron (Fig. 1).
The pattern of $\mathrm{Ru}-\mathrm{P}$ lengths is as expected: the trans diaxial pair ( $2.42,2.43 \AA$ ) are significantly longer than the cis equatorial pair ( $2 \cdot 34,2.36 \AA$ ), with the shorter $\mathrm{Ru}-\mathrm{P}(\mathrm{eq})$ trans to the longer $\mathrm{Ru}-\mathrm{S}$. The $\mathrm{P}-\mathrm{Ru}-\mathrm{P}$ angles in each facial set ( 91 to $100^{\circ}$, Table 5) are similar to those found in $\left[\mathrm{Ru}_{2} \mathrm{Cl}_{3}\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{6}\right]^{+}$(Laing \& Pope, 1976) and $\left[\mathrm{Ru}\left(\mathrm{O}_{2} \mathrm{CMe}\right)\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{4}\right]^{+}$(Ashworth, Nolte \& Singleton, 1976). The pair of axial phosphines bend toward the $\left(\mathrm{S}_{2} \mathrm{CH}\right)$ group, $\mathrm{P}(1)-\mathrm{Ru}-\mathrm{P}(2) 167^{\circ}$, to relieve the compression strains between them and the equatorial pair of phosphines. There are also significant differences between the four $\mathrm{S}-\mathrm{Ru}-\mathrm{P}(\mathrm{ax})$

Fig. 1. A projection of the cation (I) showing the numbering system and the close contacts between $\mathbf{S}(1)$ and the two phenyl rings of the axial $\mathrm{PMe}_{2} \mathrm{Ph}$ groups. C atoms are indicated only by their identity numbers.
angles. The two large angles are associated with $\mathrm{S}(1)$ because it is in close contact with the phenyl ring on each of the axial $\mathrm{P}(1)$ and $\mathrm{P}(2)$ (Tables 5 and 6 ; Fig. 1).

It was first found in $\left[\mathrm{Ru}_{2} \mathrm{Cl}_{3}\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{6}\right]^{+}$(Laing \& Pope, 1976) that for three facially arranged $\mathrm{PMe}_{2} \mathrm{Ph}$ ligands, one $\mathrm{Ru}-\mathrm{P}-\mathrm{C}(\mathrm{Me})$ angle in each ligand systematically exceeds $120^{\circ}$, that the $\mathrm{P}-\mathrm{C}$ bonds to these methyl groups are approximately parallel to each other and perpendicular to the plane of the three P atoms, and that the $\mathrm{Me} \cdots \mathrm{Me}$ separations are between 3.5 and $3.8 \AA$. The same result was observed in the purple isomer (II) (Ashworth, Singleton \& Laing, $1976 a)$ and $\left.\left[\mathrm{RuH}_{\left(\mathrm{C}_{4}\right.} \mathrm{H}_{6}\right)\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{3}\right]^{+}$(Ashworth, Singleton \& Laing, 1976b), and has been used to explain the reactivity of the parent compound $\left[\mathrm{RuH}\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{5}\right]^{+}$ (Ashworth, Nolte, Singleton \& Laing, 1977).

The two facial arrangements in (I) are shown in Fig. 2. Set $A$ has the same arrangement of methyl groups as in the three-ligand cases $\left[\mathrm{Ru}_{2} \mathrm{Cl}_{3}\left(\mathrm{PMe}_{2} \mathrm{Ph}_{6}\right]^{+}\right.$and $\left[\mathrm{RuH}\left(\mathrm{C}_{4} \mathrm{H}_{6}\right)\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{3}\right]^{+}$. Set $B$ is different. It is now the phenyl rings of $P(3)$ and $P(4)$ which stand perpendicular to the plane of the $P$ atoms, and the short separations are between these phenyl rings and the methyl group $\mathrm{C}(1.8)$ of the axial phosphine $\mathbf{P}(1)$. Once again the $\mathrm{Ru}-\mathrm{P}-\mathrm{C}$ angles are large ( $\sim 120^{\circ}$ ) for the groups involved in these non-bonded contacts.

There are two possible arrangements for the phenyl rings of the phosphine groups in the idealized facial ( $\left.\mathrm{PMe}_{2} \mathrm{Ph}\right)_{3}$ geometry. In one, the phenyl rings are related by a threefold axis; in the other, two of the phenyl rings face each other. The difference is shown schematically in Fig. 3. Arrangement $M$ is found in (I), but in the purple isomer (II) and in $\left[\mathrm{Ru}\left(\mathrm{O}_{2} \mathrm{CMe}\right)\right.$ $\left.\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{4}\right]^{+}$it is arrangement 3 which is found. In other words, two internal rotation isomers exist for a

Fig. 2. Projections of the two sets of facially arranged $\mathrm{PMe}_{2} \mathrm{Ph}$ ligands. Arrangement $A$ has three $\mathrm{P}-\mathrm{Me}$ bonds approximately parallel to each other and perpendicular to the plane of $\mathrm{P}(2), \mathrm{P}(3)$ and $\mathrm{P}(4)$. In set $B$, the phenyl rings from $\mathrm{P}(3)$ and $\mathrm{P}(4)$ are approximately perpendicular to the plane of the $P$ atoms and are in close contact with one methyl group on $P(1)$.

Fig. 3. The two possible arrangements of the phenyl rings in an idealized facial geometry for three $\mathrm{PMe}_{2} \mathrm{Ph}$ groups: 3 and $M$. Both arrangements have been found in complexes containing $\left[\mathrm{Ru}\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{3}\right]$ and $\left[\mathrm{Ru}\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{4}\right]$ fragments - see text.
compound of the class [ $\left.M(L L)\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{4}\right]^{+}$, with the implication that a second form of the orange compound (I) should be isolable. A similar phenomenon has been observed in $\left[\mathrm{RhCl}\left(\mathrm{PPh}_{3}\right)_{3}\right]$ (Bennett \& Donaldson, 1977). There are two forms, orange and red, in which the principal differences are the $\mathrm{P}-\mathrm{Rh}-\mathrm{P}$ and $\mathrm{P}-\mathrm{Rh}-\mathrm{Cl}$ angles arising from differences in the arrangements of the phenyl rings on the $\mathrm{PPh}_{3}$ groups.

The different arrangements of the methyl and phenyl groups in the two facial sets of $\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{3}$ ligands in the acetate result in the phenyl groups on the axial phosphines not being on the same side of the molecule as is found in (I). Thus, in the acetate both O atoms are shielded, but by only one phenyl ring: the phenyl ring on $\mathrm{P}(1)$ lies above $\mathrm{O}(1)$, while that on $\mathrm{P}(2)$ lies above $O(2)$ - see Tables 3 and 4, and the figure in Ashworth, Nolte \& Singleton (1976). As a result, two $\mathrm{P}-\mathrm{Ru}-\mathrm{O}$ angles are opened: $\mathrm{P}(1)-\mathrm{Ru}-\mathrm{O}(1)$ and $\mathrm{P}(2)-\mathrm{Ru}-$ $\mathrm{O}(2) 87^{\circ}$, while $\mathrm{P}(1)-\mathrm{Ru}-\mathrm{O}(2)$ and $\mathrm{P}(2)-\mathrm{Ru}-\mathrm{O}(1)$
are about $5^{\circ}$ smaller. The same effect is found in (I), but the phenyl rings on the axial phosphines both lie over the same atom, $S(1)$.

Is it possible to decide which of the two arrangements of the four $\mathrm{PMe}_{2} \mathrm{Ph}$ ligands is more stable - that in $\left[\mathrm{Ru}\left(\mathrm{S}_{2} \mathrm{CH}\right)\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{4}\right]^{+}$or that in $\left[\mathrm{Ru}\left(\mathrm{O}_{2} \mathrm{CMe}\right)\right.$ $\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{4}{ }^{+}$? The angular strain in each $\mathrm{PMe}_{2} \mathrm{Ph}$ ligand can be estimated if one assumes that a coordinated $\mathrm{PMe}_{2} \mathrm{Ph}$ ligand suffering negligible angular distortion has a mean $\mathrm{Ru}-\mathrm{P}-\mathrm{C}$ angle of $115^{\circ}$ (O’Flynn \& McDonald, 1976). Table 7 compares the deviations from ideality for the $\mathrm{Ru}-\mathrm{P}-\mathrm{C}$ angles in (I) and the related acetate. The equatorial phosphines suffer greater distortion than do the axial phosphines, and the total strain in (I) is less than that found in the acetate. While this difference is probably real, no great reliance should be placed on it as a quantitative measure because the sum of the $\mathrm{Ru}-\mathrm{P}-\mathrm{C}$ angular distortions in the highly reactive parent compound $\left[\mathrm{RuH}\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{5}\right]^{+}$is less than that in the acetate (Ashworth, Nolte, Singleton \& Laing, 1977). It is evident that the internal strain energy in this class of complexes is also taken up in distortions of $\mathrm{P}-\mathrm{Ru}-\mathrm{P}$ angles and even in stretching of $\mathrm{Ru}-\mathrm{P}$ bonds when distortions of the $\mathrm{Ru}-\mathrm{P}-\mathrm{C}$ angles can no longer accommodate the excess energy. This effect is seen in $\left[\mathrm{RuH}\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{5}\right]^{+}$where $\mathrm{P}-\mathrm{Ru}-\mathrm{P}$ angles of 88,100 and $101^{\circ}$ are found.
The bonding between the Ru atom and the $\mathrm{S}_{2} \mathrm{C}$ moiety deserves comment. In both (I) and the purple isomer (II), the two $\mathrm{Ru}-\mathrm{S}$ lengths are equal as are the

$\mathrm{S}-\mathrm{C}$ lengths. This is in contrast to the four-coordinate trans $-\left[\mathrm{PtH}\left(\mathrm{S}_{2} \mathrm{CH}\right)\left\{\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{11}\right)_{3}\right\}_{2}\right] \quad$ (Albinati, Musco, Carturan \& Strukul, 1976) and the five-coordinate $\left[\operatorname{Ir}\left(\mathrm{S}_{2} \mathrm{CPPh}_{3}\right)(\mathrm{CO})\left(\mathrm{PPh}_{3}\right)_{2}\right]^{+}$(Clark, Collins, James, Roper \& Town, 1976). In the Pt compound, the $\mathrm{S}_{2} \mathrm{CH}$ group is a monodentate ligand, with a single $\mathrm{Pt}-\mathrm{S}$ bond of $2.37 \AA$, while in the Ir compound the $S_{2} C$ moiety is asymmetrically bonded with $\mathrm{Ir}-\mathrm{S}=2.31$ and $2.38 \AA$. The $\mathrm{S}_{2} \mathrm{CH}$ group in the six-coordinate $\left[\mathrm{Re}\left(\mathrm{S}_{2} \mathrm{CH}\right)\right.$ $(\mathrm{CO})_{2}\left(\mathrm{PPh}_{3}\right)_{2}$ ] (Albano, Bellon \& Ciani, 1971) acts as a symmetrical bidentate dithioformate anion, with $\mathrm{Re}-\mathrm{S}=2.50$ and $2.53 \AA$. In $\left[\mathrm{Ru}\left(\mathrm{S}_{2} \mathrm{CH}\right)_{2}\left(\mathrm{PPh}_{3}\right)_{2}\right]$ (Kalinin, Gusev \& Struchkov, 1973) the dithioformate ligands are again bidentate but the $\mathrm{Ru}-\mathrm{S}$ bonds differ in length: $2.45,2.39 ; 2.45,2.38 \AA$, with the longer $\mathrm{Ru}-\mathrm{S}$ trans to $\mathrm{Ru}-\mathrm{P}$. Thus it is not the formal $d$ electron count, or the coordination number or geometry of the metal atom alone which determines the
nature of the bonding between the metal and the two $S$ atoms. It seems that equivalent $M-S$ bonds are associated with $d^{2} s p^{3}$ and $d s p^{3}$ hybridization (where the $d$ orbital is $d_{x^{2}-y^{2}}$ and where the two $M-\mathrm{S}$ are in similar environments and form part of a square plane).

A comparison of the structures of (I) and the purple isomer (II) shows that all the $\mathrm{Ru}-L$ bonds in the 16 electron five-coordinate complex are shorter (and presumably stronger) than the analogous bonds in the 18-electron six-coordinate isomer.

I thank the South African Council for Scientific and Industrial Research for financial support; Drs T. V. Ashworth and E. Singleton (National Chemical Research Laboratory, CSIR) for suggesting the problem and supplying the crystals, and for their cooperation and stimulating discussions; Dr G. Gafner (National Physical Research Laboratory, CSIR) for collecting the intensities; and Mrs P . Sommerville (UND) for assistance in the laboratory.
