(Received 26 January 1978; accepted 21 March 1978)

#### Abstract

The structure of $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H} .5 \mathrm{H}_{2} \mathrm{O}$ has been determined by X-ray diffraction at 90 K . The crystals are triclinic, space group $P \overline{1}$, with $a=7.8248$ (1), $b=8.2392(1), c=8.0495$ (1) $\AA, a=79.124$ (2), $\beta=$ $111.168(2), \gamma=84.812(2)^{\circ}, Z=2$. The structure contains oxonium ions $\left(\mathrm{H}_{3} \mathrm{O}^{+}\right)$and water molecules bonded to each other and to $\mathrm{CF}_{3} \mathrm{SO}_{3}^{-}$ions to form a three-dimensional network. The $\mathrm{H}_{3} \mathrm{O}^{+}$ion is hydrogenbonded to three water molecules with different lengths [2.482 (2), 2.579 (1) and 2.639 (2) $\AA$ ]. Other $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ bonds between water molecules are in the range $2 \cdot 74-2 \cdot 81 \AA$.

## Introduction

The present paper reports the structure of trifluoromethanesulphonic acid pentahydrate determined from X-ray data recorded at 90 K . This crystal structure is of particular interest since the number of water molecules per proton provides the possibility of the formation of higher hydrates, such as $\mathrm{H}_{9} \mathrm{O}_{4}^{+}$or $\mathrm{H}_{11} \mathrm{O}_{5}^{+}$. For references to crystal structure determinations of other hydrates of $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}$ see Lundgren (1978).

## Crystal data

Trifluoromethanesulphonic acid pentahydrate, $\mathrm{CF}_{3}$ $\mathrm{SO}_{3} \mathrm{H} .5 \mathrm{H}_{2} \mathrm{O}$, FW 240.13, triclinic, $a=7.8248$ (1),* $b=8.2392$ (1), $c=8.0495$ (1) $\AA, \alpha=79.124$ (2), $\beta=$ $111.168(2), \gamma=84.812(2)^{\circ}, V=468.07 \AA^{3}, Z=2$, $D_{x}=1.704 \mathrm{~g} \mathrm{~cm}^{-3}$ at $90 \mathrm{~K}, \mu\left(\mathrm{Cu} K(x)=37.91 \mathrm{~cm}^{-1}\right.$, space group $P \overline{1}$.

## Experimental

Trifluoromethanesulphonic acid pentahydrate melts congruently at $-46^{\circ} \mathrm{C}$ (Karlsson, 1978; Delaplane, Lundgren \& Olovsson, 1975). For experimental details of crystal preparation, data collection and data reduction see Lundgren (1978).

The cell dimensions were determined by leastsquares refinement from the measured $2 \theta$ values of 92 reflexions from three different crystals mounted around [100], [010] and [001] respectively.

[^0]Intensities for layers $h 0 l$ to $h 7 l$ were recorded from a crystal mounted around [010]. The crystal was cylindrical with a diameter of 0.29 mm and a length of 0.26 mm .1727 independent reflexions were measured. The intensities of the test reflexions monitored in each layer showed no systematic variations.

A complementary set of 1070 independent reflexions (layers 0 kl to 4 kl ) was similarly measured from a second cylindrical crystal mounted around [100]. This set was used only to determine the relative scale factors between the layers in the previous data set. A $\delta m$ comparison of the two sets (Abrahams \& Keve, 1971; Lundgren, 1978) made after the interlayer scaling procedure indicated that the e.s.d.'s based on counting statistics were underestimated by a factor of 1.8 and they were thus changed accordingly.

## Structure determination and refinement

The structure was solved by Patterson methods, and refined with the full-matrix least-squares program $U P A L S$. The function minimized was $\sum w\left(F_{o}^{2}-F_{c}^{2}\right)^{2}$, where $w^{-1}=\sigma^{2}\left(F^{2}\right)$. After refinement of the nonhydrogen atoms, the H atoms were located from difference maps based on reflexions with $\sin \theta / \lambda<0.45$ $\AA^{-1}$. A final refinement of 163 variables included a scale factor, an isotropic extinction parameter, positional parameters for all atoms, individual anisotropic thermal parameters for the non-hydrogen atoms and isotropic temperature factors for H. The final $R\left(F^{2}\right)=$ $\sum\left|F_{0}^{2}-F_{c}^{2}\right| / \sum F_{o}^{2}=0.049, R_{w}\left(F^{2}\right)=\left[\sum w\left(F_{o}^{2}-\right.\right.$ $\left.\left.F_{c}^{2}\right)^{2} / \sum w F_{o}^{4}\right]^{1 / 2}=0^{0} .073$, and $R(F)=0.028$. The refined value of the isotropic extinction parameter $g$ (Coppens \& Hamilton, 1970) was $7.0(2) \times 10^{3}$. The e.s.d. of an observation of unit weight was $s=\left[\sum w\left(F_{o}^{2}-F_{c}^{2}\right)^{2} /(m\right.$
$-n)]^{1 / 2}=1.87$, where $m$ is the number of observations and $n$ the number of parameters varied.

Scattering factors for $\mathrm{S}, \mathrm{F}, \mathrm{C}$ and $\mathrm{O}^{0.33-}$ (obtained by interpolating $\mathrm{O}^{0}$ and $\mathrm{O}^{1-}$ tables) were from Hanson, Herman, Lea \& Skillman (1964). The spherical scattering factors of Stewart, Davidson \& Simpson (1965) were used for $H$. An anomalous-dispersion correction was included for the non-hydrogen atoms (Cromer \& Liberman, 1970). The programs used for all computations with IBM 370/155 and 1800 computers have been described by Lundgren (1976). The final positional parameters for the non-hydrogen atoms are given in Table 1.*

* Lists of structure factors, thermal parameters and H atom positional parameters have been deposited with the British Library Lending Division as Supplementary Publication No. SUP 33522 ( 15 pp.). Copies may be obtained through The Executive Secretary, International Union of Crystallography, 5 Abbey Square, Chester CH1 2HU, England.

## Description of the structure

A stereoscopic illustration of the structure is shown in Fig. 1. The hydrogen-bond distances are included in Fig. 2 and also listed with angles in Table 2.

The hydrogen-bond distances and the positions of the H atoms indicate an ionic formulation of the compound. The oxonium ion and three of the crystallographically non-equivalent water molecules are hydrogen-bonded to one another to form centro-

Fig. 2. Hydrogen-bond distances $(\AA) . H$ atom positions and thermal parameters are as obtained from least-squares refinement. The distances refer to non-hydrogen atoms. Thermal ellipsoids enclose $50 \%$ probability.

Fig. 1. Stereoscopic ORTEP (Johnson, 1965) illustration of the crystal structure of $\mathrm{H}_{3} \mathrm{O}^{+} \mathrm{CF}_{3} \mathrm{SO}_{3}^{-} \cdot 4 \mathrm{H}_{2} \mathrm{O}$. The O atoms of the oxonium ion (1) and the water molecules (2-5) are numbered. The H atoms have been omitted. Covalent bonds are filled and hydrogen bonds open. The thermal ellipsoids are scaled to enclose $60 \%$ probability.

symmetric hexagons. These hexagons form zigzag chains along $\mathbf{b}$, in a plane parallel to (010). Different chains of hexagons are bonded together via the fourth water molecule to form irregular layers parallel to ( 10 I ). $\mathrm{CF}_{3} \mathrm{SO}_{3}^{-}$ions are interspersed in the cavities formed between these layers. Two of the sulphonate $O$ atoms are hydrogen-bonded to water molecules. A three-dimensional network of hydrogen bonds is thus formed.

The role of the $\mathrm{CF}_{3} \mathrm{SO}_{3}^{-}$ion as a link between hydrogen-bonded layers in the present structure differs from that found in the hemi-, mono- and dihydrates, where water molecules and sulphonate groups form infinite hydrogen-bonded layers with no hydrogen-bond interactions between layers. The $-\mathrm{CF}_{3}$ groups point out at right-angles to the layers. In the tetrahydrate, the $-\mathrm{CF}_{3}$ groups also point out in both directions from the hydrogen-bonded layers, but one of the nine different hydrogen bonds in this structure is used to connect the different layers. Finally, in the present structure the $\mathrm{CF}_{3} \mathrm{SO}_{3}^{-}$ions are parallel to the hydrogen-bonded layers of water molecules, and the sulphonate groups are used entirely for interconnecting adjacent layers.

## The oxonium ion and the water molecules

The oxonium ion, $\mathrm{H}_{3} \mathrm{O}^{+}$, is hydrogen-bonded to three water molecules by rather short bonds in a pyramidal arrangement (Fig. 2). The $\mathrm{O}(w 1) \cdots \mathrm{O}$ distances are 2.482 (2), 2.579 (1) and 2.639 (2) $\AA$. $\mathrm{H}_{2} \mathrm{O}(w 2)$, which participates in the short $2.48 \AA$ bond, also has a pyramidal bonding arrangement. All other water molecules have a tetrahedral environment. The
complex formed by $\mathrm{H}_{3} \mathrm{O}^{+}$and its three nearest water molecules can be regarded as an $\mathrm{H}_{9} \mathrm{O}_{4}^{+}$complex. The average $\mathrm{H}_{3} \mathrm{O}^{+} \ldots \mathrm{O}(w)$ distance is $2.57 \AA$, which is comparable to distances found in $\mathrm{H}_{9} \mathrm{O}_{4}^{+} \mathrm{Cl}^{-} .2 \mathrm{H}_{2} \mathrm{O}$ $(2.52 \AA)$ (Taesler \& Lundgren, 1978) and $\mathrm{H}_{9} \mathrm{O}_{4}^{+-}$ $\mathrm{CF}_{3} \mathrm{SO}_{3}^{-}(2.54 \AA)$ (Lundgren, 1978). The layers of water molecules in the structure could then be described as consisting of chains of $\mathrm{H}_{9} \mathrm{O}_{4}^{+}$ions linked via the remaining water molecules. The hydrogen bonds formed by the other water molecules are only slightly longer than the $\mathrm{O}(w 1) \cdots \mathrm{O}(w 4)$ bond within the complex, however. The difference between the bonds $\mathrm{O}(w 4) \cdots \mathrm{O}(w 1)$ and $\mathrm{O}(w 4) \cdots \mathrm{O}(w 5)$ is only $0.12 \AA$, which is less than the difference between the bonds $\mathrm{O}(w 1) \cdots \mathrm{O}(w 4)$ and $\mathrm{O}(w 1) \cdots \mathrm{O}(w 2)$ within the complex $(0.16 \AA)$. The formulation $\mathrm{H}_{9} \mathrm{O}_{4}^{+}$could, of course, be used for any complex consisting of an oxonium ion hydrogen-bonded to three water molecules but, for this formulation to be useful as a concept in describing a structure, it should be a requirement that the complex be well separated from other water molecules. The formulation $\mathrm{H}_{9} \mathrm{O}_{4}^{+}$would therefore seem less natural in the present case.

## Hydrogen atoms

Distances and angles involving H atoms, though inaccurately determined, are all near their expected values. The $\mathrm{O}-\mathrm{H}$ distances and $\mathrm{H}-\mathrm{O}-\mathrm{H}$ angles within the $\mathrm{H}_{3} \mathrm{O}^{+}$ion are $0.84,0.86$ and 0.86 (3) $\AA$ and 106, 111 and 116 (2) ${ }^{\circ}$ respectively. The $\mathrm{O}-\mathrm{H}$ distances in the water molecules are $0.79-0.89$ (3) $\AA$; the $\mathrm{H}-\mathrm{O}-\mathrm{H}$ angles are $98-107(2)^{\circ}$. The $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ angles are in
the range 165-176 (2) ${ }^{\circ}$, except for the angle $\mathrm{O}(w 5)-$ $\mathrm{H} \cdots \mathrm{O}$ (2) ( $147^{\circ}$ ) (Fig. 2), where the $\mathrm{O}(w 2) \cdots$ $\mathrm{O}(w 5) \cdots \mathrm{O}(2)$ angle is also very large ( $143 \cdot 2^{\circ}$ ). The isotropic temperature factors for the H atoms all refined to values within the range $2 \cdot 5-4 \cdot 1$ (5) $\AA^{2}$.

## The trifluoromethanesulphonate ion

The $\mathrm{CF}_{3} \mathrm{SO}_{3}^{-}$ion has a staggered conformation with pseudo $C_{3 v}$ symmetry. The $\mathrm{F}-\mathrm{C}-\mathrm{S}-\mathrm{O}$ torsion angles for F and O in the trans position are $177.69,178.70$ and $179.16^{\circ}$ respectively. The $-\mathrm{CF}_{3}$ group has an approximately regular tetrahedral conformation with an average $\mathrm{C}-\mathrm{F}$ distance of $1.329 \AA$. The average $\mathrm{S}-\mathrm{C}-\mathrm{F}$ and $\mathrm{F}-\mathrm{C}-\mathrm{F}$ angles are 110.6 and $108.9^{\circ}$ respectively.

The sulphonate group accepts four hydrogen bonds. $O(2)$ and $O(3)$ each accept two hydrogen bonds, whereas $\mathrm{O}(1)$ does not participate in hydrogen bonding. This is also reflected in the $\mathrm{S}-\mathrm{O}$ bond distances: $\mathrm{S}-\mathrm{O}(1)$ is $0.02 \AA$ shorter than the other two $\mathrm{S}-\mathrm{O}$ distances. The sulphonate group has an average $\mathrm{S}-\mathrm{O}$ distance of $1.444 \AA$, an average $\mathrm{O}-\mathrm{S}-\mathrm{O}$ angle of $114.7^{\circ}$, an average $\mathrm{C}-\mathrm{S}-\mathrm{O}$ angle of $103.5^{\circ}$ and a C-S distance of $1.829 \AA$. These values compare well with the corresponding values obtained in the hemi-, mono-, di- and tetrahydrates of $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}$. The average distances and angles for the five independently determined $\mathrm{CF}_{3} \mathrm{SO}_{3}^{-}$ions are: $\mathrm{S}-\mathrm{O}$ 1.445 (9), $\mathrm{C}-\mathrm{S}$ $1.827(5), \mathrm{C}-\mathrm{F} \quad 1.326$ (6) Á, $\mathrm{O}-\mathrm{S}-\mathrm{O} 114.6$ (16), $\mathrm{C}-\mathrm{S}-\mathrm{O} \quad 103.9$ (7) and $\mathrm{S}-\mathrm{C}-\mathrm{F} \quad 110.2$ (6) ${ }^{\circ}$. (The e.s.d.'s express the deviations of the individual values from the mean.) The large difference ( $10.7^{\circ}$ ) between the $\mathrm{O}-\mathrm{S}-\mathrm{O}$ and $\mathrm{C}-\mathrm{S}-\mathrm{O}$ bond angles is typical for substituted sulphonate groups (Greenberg \& Okaya, 1969).

The largest spread is found for values involving O atoms which participate in different hydrogen-bonding interactions, especially the $\mathrm{S}-\mathrm{O}$ distances and $\mathrm{O}-\mathrm{S}-\mathrm{O}$ angles. In the fifteen independent $\mathrm{S}-\mathrm{O}$ bonds, one O atom is not hydrogen-bonded at all, eight accept one hydrogen bond, and six accept two hydrogen bonds. In Fig. 3, the S-O lengths are plotted versus the number of hydrogen bonds accepted by the O atoms. The average S-O distances are $1.429,1.442$ and $1.451 \AA$ for zero, one and two accepted hydrogen bonds.

The three longest $\mathrm{S}-\mathrm{O}$ distances for O atoms accepting one hydrogen bond are found for the monohydrate (Spencer \& Lundgren, 1973). These values may well be affected by an additional source of systematic error: the data-collection procedure used for this particular study was not optimized for a diffractometer with Weissenberg geometry. Neither, in this case, could positional and thermal parameters for the H atoms be refined successfully. This can also be taken as a measure of the quality of the data. If the three monohydrate S-O distances are removed, the corresponding average is $1.438 \dot{\mathrm{~A}}$.

Fig. 3. Plot of $\mathrm{S}-\mathrm{O}$ bond length versus number of hydrogen bonds accepted by the O atoms of the $\mathrm{CF}_{3} \mathrm{SO}_{3}^{-}$ion in $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}$ hydrates.

If $\mathrm{S}-\mathrm{O}$ distances corrected for thermal riding motion are used, the mean S-O distances are $1.435,1.446$ and $1.457 \AA$ respectively.

The general conclusion to be drawn from Fig. 3 is that the S-O length increases by $0.01 \AA$ for each hydrogen bond the O atom accepts.

I thank Professor I. Olovsson for the facilities made available to me and Mr H . Karlsson for his skilled technical assistance. This work was supported in part by grants from the Swedish Natural Science Research Council, which are gratefully acknowledged.
