twist (Berry, 1960) in these two stereochemistries. The more trigonal-distorted square-pyramidal stereochemistry of (II) may be related to the smaller bite angle of 77.0 of the bpy ligand (Johnson, Beineke \& Jacobson, 1971) relative to that of $89.2^{\circ}$ in the dpyam ligand (Stephens, 1972), but it is then difficult to see how the bite angle influences the smaller value of $\mathrm{N}(1)-\mathrm{Cu}-\mathrm{N}(3)$ in (I).

The pyridine rings of the dpyam and bpy ligands are reasonably planar in (I) and (II), respectively; in (I) they are inclined at an angle of $4.29^{\circ}$ to each other while in (II) they are twisted about the $\mathrm{C}(11)-\mathrm{C}(12)$ bond by an angle of $2 \cdot 15^{\circ}$, both in reasonable agreement with previously observed values (Johnson, Beineke \& Jacobson, 1971; Stephens, 1972).

The authors acknowledge the award of a Department of Education grant (to NJR), and thank Drs G. Sheldrick and S. Motherwell (Cambridge University) for the use of their X-ray crystallography programs, the Computer Bureau, UCC, for computing facilities and Dr M. Elder of the SRC Microdensitometer Service for intensity determinations.

# Crystal and Molecular Structure of (3,3'-Dimethyl-2,2'-bipyridyl)methylmercury(II) Nitrate; a Complex That May Have Weak Intramolecular $\boldsymbol{\pi}$-Coordination 

By Allan J. Canty, $\dagger$ Narongsak Chaichit, Bryan M. Gatehouse* and Anthony Marker $\dagger$<br>Chemistry Department, Monash University, Clayton, Victoria 3168, Australia

(Received 14 March 1978; accepted 5 June 1978)

#### Abstract

$\mathrm{C}_{13} \mathrm{H}_{15} \mathrm{HgN}_{3} \mathrm{O}_{3}$ is monoclinic, $a=10.521(5), b=9.310(5), c=16.570(8) \AA, \beta=106.6(1)^{\circ}, Z=4$, space group $P 2_{1} / c$. The structure was solved by Patterson and Fourier techniques using 1560 counter-measured observed reflections and refined by the full-matrix least-squares method to $R=0.061$. The complex has a bent $\mathrm{C}(1)-\mathrm{Hg}-\mathrm{N}(1)$ group $\left[172.7(5)^{\circ}\right.$ ] with $\mathrm{Hg}-\mathrm{C}(1) 2.01$ (1) and $\mathrm{Hg}-\mathrm{N}(1) 2 \cdot 11$ (1) $\dot{\mathrm{A}}$, weak interaction between Hg and nitrate O atoms, and evidence suggesting the presence of a weak intramolecular $\pi$-interaction between Hg and the second pyridyl ring, with $\mathrm{Hg}-\mathrm{C}\left(2^{\prime}\right) 3.11(1), \mathrm{Hg}-\mathrm{N}\left(1^{\prime}\right) 3.29$ (1) $\AA$ and an angle of $100 \cdot 5^{\circ}$ between the planes of the pyridyl rings.

## Introduction

Methylmercury(II) forms complexes involving irregular three-coordination for Hg with $2,2^{\prime}$-bipyridyl (Canty, Marker \& Gatehouse, 1975; Canty \& Gatehouse, 1976) and methyl-substituted $2,2^{\prime}$-bipyridyls, except for 3, ${ }^{\prime}$ 'dimethyl-2, $2^{\prime}$ '-bipyridyl ( $3,3^{\prime}$-dmbpy) where steric interaction between $3,3^{\prime}$-dimethyl groups prevents

[^0]coplanarity of the pyridyl rings required by chelation (Canty \& Marker, 1976). Coordination of only one N to methylmercury(II) has been shown by ${ }^{1} \mathrm{H}$ NMR spectroscopy for $\left[\mathrm{MeHg}\left(3,3^{\prime}-\mathrm{dmbpy}\right)\right] \mathrm{NO}_{3}$ (Canty \& Marker, 1976), but ${ }^{199} \mathrm{Hg}$ NMR studies of $\mathrm{MeHg}^{11}$ complexes of pyridine, $2,2^{\prime}$-bipyridyl, and related substituted ligands suggest that there may be weak $\pi$ interaction between Hg and the second aromatic ring in this complex and also in the analogous 2-benzylpyridine complex (Canty, Marker, Barron \& Healy, 1978). Chemical shifts for the Hg atom in these two complexes are approximately 90 ppm upfield from
values for complexes with unidentate ligands of similar basicity, e.g. pyridine; a similar upfield shift for dimethylmercury in benzene ( 50.4 ppm upfield from neat $\mathrm{Me}_{2} \mathrm{Hg}$ ) has been attributed to weak $\pi$-interaction with benzene (Sens, Wilson, Ellis \& Odom, 1975). A weak $\pi$-interaction does occur in some $\gamma$-substituted propylmercury complexes, e.g. $\mathrm{ClHgCH}_{2} \mathrm{C}(\mathrm{Me})-$ $\left(\mathrm{OMe}^{2}\right) \mathrm{CH}_{2}(p-\mathrm{OMePh})$ which has $\mathrm{Hg} \ldots \mathrm{Ph} 3.05 \AA$ (Kiefer, Waters \& Carlson, 1968), and in order to determine whether weak $\pi$-interactions occur in the chemistry of $\mathrm{MeHg}^{11}$ we have determined the crystal and molecular structure of $\left[\mathrm{MeHg}\left(3,3^{\prime}-\mathrm{dmbpy}\right)\right] \mathrm{NO}_{3}$.

## Experimental

Crystals of $\mid \mathrm{MeHg}\left(3,3^{\prime}\right.$-dmbpy $) \mid \mathrm{NO}_{3}$ for this study were available from the initial preparation used for microanalysis and spectroscopic examination (Canty \& Marker, 1976).

## Crystal data

$\mathrm{C}_{13} \mathrm{H}_{15} \mathrm{HgN}_{3} \mathrm{O}_{3}, M_{r}=461.87$, monoclinic, $a=$ 10.521 (5), $b=9.310$ (5), $c=16.570$ (8) $\AA, \beta=$ $106.6(1)^{\circ}, U=1555.39 \AA^{3}, D_{m}=1.97$ (2) (by flotation in a $\mathrm{CCl}_{4} / \mathrm{CH}_{3} \mathrm{I}$ mixture), $D_{c}=1.97 \mathrm{~g} \mathrm{~cm}^{-3}, Z$ $=4, F(000)=872$. Data collected at $20^{\circ} \mathrm{C}$, Mo $K$ a radiation $(\lambda=0.7107 \AA), \mu($ Mo $K())=117.9 \mathrm{~cm}^{-1}$. Space group $P 2_{1} / c$ (No. 14, $C_{2 h}^{5}$ ) from systematic absences: $h 0 l, l$ odd, $0 k 0, k$ odd. Unit-cell parameters were determined using a Philips PW 1100 automatic four-circle diffractometer equipped with a graphite monochromator by a method described previously (Gatehouse \& Miskin, 1974).

## Intensity measurements

Intensity data were collected using the diffractometer above and a colourless to white crystal of dimensions $0.05 \times 0.11 \times 0.11 \mathrm{~mm}$ that had been checked for cracking or twinning using a polarizing microscope. The crystal was mounted on a silica capillary using 'Resiweld' epoxy cement and centred on the goniometer using high-angle reflections selected from an initial rapid data collection. Three standard reflections monitored at 90 min intervals showed no significant systematic variation in intensity.
Data were collected by the $\omega$-scan technique with a symmetric scan width of $\pm 0.5^{\circ}$ in $\omega$ from the calculated Bragg angle, with an allowance for dispersion, at a scan rate of $0.02^{\circ} \mathrm{s}^{-1}$. No reflection was sufficiently intense to warrant the insertion of an attenuation filter. The data were processed with a program written specifically for the PW 1100 diffractometer (Hornstra \& Stubbe, 1972). The backgroundcorrected intensities were assigned standard deviations
according to: $\sigma(I)=\mid C T+\left(t_{c} / t_{b}\right)^{2}\left(B_{1}+B_{2}\right)+$ $\left.(q I)^{2}\right|^{1 / 2}$ where $C T$ is the total integrated peak count obtained in scan time $t_{c} ; B_{1}$ and $B_{2}$ are background counts each obtained in time $\frac{1}{2} t_{b}$, and $I=C T$ $\left(t_{c} / t_{b}\right)\left(B_{1}+B_{2}\right) ; q$ was 0.04 and is an allowance for 'machine errors'. Values of $I$ and $\sigma(I)$ were then corrected for Lorentz and polarization effects. An absorption correction was applied based on the indexed crystal faces (100), ( 100 ), ( 010 ), ( $0 \overline{1} 0$ ), ( $10 \overline{3}$ ) and (103), and direction cosines calculated for the PW 1100 data. Maximum and minimum transmission factors were 0.6393 and 0.3557 respectively. 4171 reflections were measured to $2 \theta\left(\mathrm{Mo} \mathrm{K}(\mathrm{I})=56^{\circ}\right.$; of these, 614 were rejected as being systematically absent or having zero $F$ or $I$. A further 141 were multiple observations and the measure of agreement between these, $R$, was 0.03 where $R$ is given by $\left(\sum\left\{N \sum \mid w\left(F_{\mathrm{av}}-F\right)^{2}\right]\right\} / \sum[(N-1)$ $\left.\left.\times \sum\left(w F^{2}\right)\right]\right)^{1 / 2}$. [The inner summations are over the $N$ equivalent reflections averaged to give $F_{\mathrm{av}}$, and the outer summations are over all unique reflections (Sheldrick, 1976).] This left 3416 unique reflections of which 1560 obeyed the condition $I \geq 3 \sigma(I)$ and were used in the subsequent calculations.

## Structure determination and refinement

The structure was solved by Patterson and Fourier techniques; the Hg atom position was refined and all non-hydrogen atoms were located in the subsequent difference Fourier synthesis. The function minimized in the full-matrix least-squares refinement was $\sum w\left(\left|F_{o}\right|-\right.$ $\left.\mid F_{c}!\right)^{2}$, where $w$ is the weight $\left[1 / \sigma^{2}\left(F_{o}\right) \mid\right.$. All nonhydrogen atoms were refined anisotropically to give $R$ $=0.071$. Although a difference Fourier synthesis revealed some H atom positions, all coordinates were

calculated according to the geometry of the C atom to which they are bonded, and with $\mathrm{C}-\mathrm{H}=1.08 \AA$. Final refinement with isotropic H atoms riding on their respective C atoms gave $R=0.061$ and $R^{1}=0.042$, where $R^{1}=\left[\sum w\left(\left|F_{o}\right|-\left|F_{c}\right|\right)^{2} / \sum w\left|F_{o}\right|^{2}\right]^{1 / 2}$.* The final difference synthesis had no major characteristic greater than that ( 1.6 e $\AA^{-3}$ ) in the vicinity of the Hg atom. The largest shift to e.s.d. ratio in the final cycle was 0.023 for the $C(3) y$ parameter.

Final parameters for all atoms are listed in Tables 1 and 2. Atomic scattering factors, corrected for anomalous dispersion, were taken from Cromer \& Mann (1968) and Cromer \& Liberman (1970).

All calculations were carried out using the Monash University B 6700 computer; the major programs used were SHELX 76 (Sheldrick, 1976), ORFFE (Busing, Martin \& Levy, 1964), MEANPL (Blow, 1960) and ORTEP (Johnson, 1965).

[^1]
## Discussion of the structure

The structure consists of $\left[\mathrm{MeHg}\left(3,3^{\prime}-\mathrm{dmbpy}\right)\right]^{+}$cations and nitrate anions as shown in Fig. 1 where the numbering scheme follows that used for the $2,2^{\prime}$ bipyridyl complex (Canty \& Gatehouse, 1976). Interatomic distances for the anion and cation, together with other distances around the Hg atom, are given in Table 3. A packing diagram is given in Fig. 2. The planes of the two pyridyl rings are at an angle of $100.5^{\circ}$ to one another, and at angles of 92.7 and $52.9^{\circ}$ to the plane of the nitrate ion. Equations for the three planes are given in Table 4 together with the distances of relevant atoms from them. The torsion angle $\mathrm{C}(6)-\mathrm{N}(1)-\mathrm{Hg}-$ $\mathrm{C}(1)$ is $-162(4)^{\circ}$, and $\mathrm{C}(2)-\mathrm{N}(1)-\mathrm{Hg}-\mathrm{C}(1)$ is $20(5)^{\circ}$, where the sign of the angle follows accepted convention (Klyne \& Prelog, 1960). The angles at Hg are: $\quad \mathrm{C}(1)-\mathrm{Hg}-\mathrm{N}(1) \quad 172.7$ (5), $\quad \mathrm{C}(1)-\mathrm{Hg}-\mathrm{N}\left(1^{\prime}\right)$ 108.3 (5) and $\mathrm{N}(1)-\mathrm{Hg}-\mathrm{N}\left(1^{\prime}\right) 64.4$ (4) ${ }^{\circ}$. The nitrate ion angles are: $\mathrm{O}(1)-\mathrm{N}(2)-\mathrm{O}(2) 117(1), \mathrm{O}(1)-\mathrm{N}(2)-$ $\mathrm{O}(3) 123$ (1) and $\mathrm{O}(2)-\mathrm{N}(2)-\mathrm{O}(3) 120(1)^{\circ}$.

The nitrate bond lengths and angles suggest a small but real distortion away from the $D_{3 h}$ symmetry of an

isolated $\mathrm{NO}_{3}^{-}$ion. The shortest $\mathrm{Hg}-\mathrm{O}$ distances involve $\mathrm{O}(1)$ and $\mathrm{O}(2)\left|\mathrm{O}(1)-\mathrm{Hg}-\mathrm{O}(2)=43 \cdot 6(3)^{\circ}\right|$ and a small closing of the $\mathrm{O}(1)-\mathrm{N}(2)-\mathrm{O}(2)$ angle is observed, together with a small lengthening of $\mathrm{N}(2)-\mathrm{O}(1)$ and $\mathrm{N}(2)-\mathrm{O}(2) . \mathrm{O}(3)$ is 3.09 (1) $\AA$ from Hg . Thus weak interaction is present between the Hg atom and the nitrate O atoms. Fig. 1 shows the relationship

between Hg and the nearest nitrate ions. Grdenic (1965) considers the van der Waals radius of Hg to be $1.50 \AA$, but suggests that if the radius is $<1.73 \AA$ some form of bonding is present. Taking the van der Waals radius for O as $1.40 \AA$ (Pauling, 1960), the two $\mathrm{Hg}-\mathrm{O}$ radii sums are 2.90 and $3.13 \AA \dot{A}$; these are $c a 0.0-0.3$ $\AA$ greater than the observed $\mathrm{Hg}-\mathrm{O}$ distances of 2.84 (1), 2.86 (1) and 2.90 (1) $\dot{\AA}$. An additional O is 3.09 (1) A from Hg .

A value of $1.75 \AA$ for the radius of $\mathrm{Hg}^{\text {II }}$ has been suggested from close contacts between Hg atoms in $\left[\mathrm{Et}_{4} \mathrm{~N}_{2} \mathrm{Hg}_{3} M \mathrm{Cl}_{10}(M=\mathrm{Pd}, \mathrm{Pt})\right.$ (Barr, Goldstein, Hairs, McPartlin \& Markwell, 1974), and in the phenylmercury(II) creatinine complex

## [ $\mathrm{PhHgNHCNMeCH} \mathrm{CONH}_{2} \mathrm{CONFh}^{2} \mathrm{NO}_{3}$

Hg atoms within the cation are 3.407 (2) $\AA$ apart (Canty, Fyfe \& Gatehouse, 1978). From physical and crystallographic studies of organomercury(II) quinolin8 -olates it has been suggested that the van der Waals radius of Hg approaches $2.0 \AA$ (Bertino, Deacon \& Miller, 1978).

The distances $\mathrm{Hg}-\mathrm{C}(1)$ and $\mathrm{Hg}-\mathrm{N}(1)$ are similar to those in other $\mathrm{MeHg}^{11}$ complexes involving neutral N donor ligands (Table 5). The distance from Hg to the midpoint of the $\mathrm{C}\left(2^{\prime}\right)-\mathrm{N}\left(1^{\prime}\right)$ bond is $3.13 \AA$ and is longer than the $3.05 \AA$ found for the distance of Hg to the midpoint of a $\mathrm{C} \ldots \mathrm{C}$ bond in the phenyl ring in $\mathrm{ClHgCH}_{2} \mathrm{CH}(\mathrm{Me}) \mathrm{OMeCH}_{2}(p-\mathrm{OMePh})$ where the presence of a $\pi$-interaction has been shown from conformational analysis by ${ }^{1} \mathrm{H}$ NMR spectroscopy (Kiefer, Waters \& Carlson, 1968). If a weak $\pi$-interaction is present in the solid state, it is apparently
weaker than the $\mathrm{Hg} \cdots \mathrm{O}$ interactions as the methyl group bonded to Hg is bent away from the nitrate O atoms towards the second pyridyl ring, whereas if appreciable $\mathrm{Hg} \cdots$ pyridyl interaction were present the opposite would be expected.

We thank the Commonwealth Development Bank for a postdoctoral fellowship (AM), the Australian Development Assistance Plan (NC) and the Australian Research Grants Committee for financial support.

# Structure Cristalline de l'Acide Ethanediylidènetétrathiotétraacétique 

Par Joël Canonne, Jean-Claude Boivin, Guy Nowogrocki et Daniel Thomas

Laboratoires de Physico-Chimie des Solutions et de Cristallochimie, Ecole Nationale Supérieure de Chimie de Lille, BP 40, 59650 Villeneuve d'Ascq, France
(Reçu le 28 mars 1978, accepté le 30 mai 1978)
Ethanediylidenetetrathiotetraacetic acid, $\mathrm{C}_{10} \mathrm{H}_{14} \mathrm{O}_{8} \mathrm{~S}_{4}$, crystallizes in the triclinic space group $P \overline{1}$ with one molecule in the unit cell of dimensions $a=7.785(3), b=10.688$ (4), $c=5.195$ (2) $\AA$, $"=92.43$ (4), $\beta=$ $102.71(4), \gamma=114.52(4)^{\circ}$. The structure was solved by direct methods and refined by a full-matrix leastsquares procedure to a final $R$ value of 0.047 for 1815 observed reflexions. Each molecule is hydrogenbonded to four neighbouring molecules, whose centres lie in (111) planes, by single $\mathrm{OH} \ldots \mathrm{O}$ bonds to form three types of rings. One of these connects four carboxyl groups together to form a cyclic hydrogen-bonded planar system.

## Introduction

Dans le cadre d'une étude générale des structures d'acides polythiopolycarboxyliques, nous avons établi celles des acides méthylènedithiodipropionique et
méthylènedithiodiacétique (Canonne, Boivin, Nowogrocki \& Thomas, 1977, 1978). L'acide éthanediylidènetétrathiotétraacétique (ETTA) est un tétraacide dont les constantes d'acidité sont très proches (Nowogrocki, Canonne \& Wozniak, 1976). Il possède
