#### Abstract

C}_{6} \mathrm{H}_{11} \mathrm{NO}_{2} . \mathrm{HCl}, M_{r}=165 \cdot 5\), monoclinic, $P 2_{1} / c, a=12.506$ (15), $b=6.471$ (5), $c=10.826$ (12) $\AA, \beta=98.91(5)^{\circ}, Z=4 . D_{m}=1 \cdot 27, D_{x}=1.269$ $\mathrm{Mg} \mathrm{m}^{-3}$. Final $R=0.11$. The compound exists in the trans form. The structure is loosely packed and the $\mathrm{Cl}^{-}$ion has three alternative disordered sites of low occupancy and a predominant large-occupancy site. The side-chain conformation does not correspond to other reported methionine structures.

Introduction. Biological antagonists owe their action to their close structural similarity to normal metabolites. Analyses of the hydrochloride of $p$-nitrophenylalanine (Chacko, Swaminathan, Parthasarathy \& Natarajan, 1978), an antagonist of phenylalanine, and of thienylserine (Swaminathan \& Chacko, 1979), an antagonist of serine and threonine have been reported. The hydrochloride of 2-butenylglycine (I), an antagonist of methionine, could have a cis or trans conformation about the $\mathrm{C}^{\nu}-\mathrm{C}^{\delta}$ bond. X-ray analysis was necessary to establish the conformation. It has been shown (Skinner, Edelson \& Shive, 1961) that the cis form of (I) is a more effective competitive antagonist of methionine in $E$. coli than the trans form.

(I)

Flat, plate-like crystals were formed from a solution of 2-butenylglycine in dilute hydrochloric acid supplied by Nutritional Biochemicals Corporation, USA. Preliminary studies were carried out with Weissenberg photographs. The cell dimensions were determined from the $2 \theta$ values of 30 reflections on a Picker fourcircle diffractometer ( $\mathrm{Cu} K \alpha$ radiation, $\lambda=1.54178 \AA$, $\mu=3.50 \mathrm{~mm}^{-1}$. A crystal $0.1 \times 0.2 \times 0.2 \mathrm{~mm}$ was used for data collection with $b$ coinciding with the

[^0]$\varphi$ axis. The $\theta-2 \theta$ scan mode was employed with $2^{\circ}$ $\min ^{-1}$ scan speed. The scan range was $2^{\circ}$ with backgrounds measured on either side of the peak for 10 s . 1407 reflections were measured with $I>2 \sigma(I)$ within the range $2 \theta \leq 130^{\circ}$. The data were corrected for Lorentz and polarization factors and initially scaled by Wilson's method.

The Cl atom was located from a Patterson map ( $R=0 \cdot 5$ ). A Fourier synthesis revealed all the nonhydrogen atoms and also showed that the side-chain of this amino acid exists in the trans form. The structure was refined isotropically with the blockdiagonal least-squares program of Shiono (1968) to an $R$ of $0 \cdot 16$. A difference map computed at this stage showed three small ( $<2$ e $\AA^{-3}$ ) peaks close to the Cl atom, indicative of disorder. The intensities (as well as the initial Weissenberg photographs) showed that the reflections were unusually weak for a heavy-atom derivative and also indicated possible disorder. Further, the low density indicated that the structure was loosely packed.

By introducing these extra peaks with partial occupancy factors there was a significant drop in $R$ to 0.14 . The partial occupancy factors for the three alternative positions were near 0.085 with the main Cl atom (predominant position) having an occupancy of 0.745 . Further refinement was carried out with the full-matrix program LALS (Gantzel, Sparks \& Trueblood, 1961) with isotropic temperature factors for the disordered

Cl atom and anisotropic temperature factors for other non-hydrogen atoms. The H atoms located from the difference map were included in fixed positions. The occupancy factors of the disordered Cl were also fixed. Refinement converged to $R=0 \cdot 11$. Hughes (1941) weights were used ( $1 / w^{2}$, where $w=\left|F_{o}\right|$ for $\left|F_{o}\right| \geq 4.0$ and $w=4.0$ for $\left.\left|F_{o}\right|<4.0\right)$.

Scattering factors were taken from International Tables for X-ray Crystallography (1962) and an $f^{\prime}(=0.3)$ correction was applied to $\mathrm{Cl}^{-}$. Tables 1 and $2^{*}$ give the final atomic parameters (these correspond to the l-configuration).

Discussion. The bond lengths and angles (Fig. 1) compare well with standard values. The carboxyl group exists as COOH with the N atom in the $\mathrm{NH}_{3}^{+}$state and

chloride as $\mathrm{Cl}^{-}$. As is usual in amino acids, the $\mathrm{C}=\mathrm{O}$ [C(1)-O(1)] bond occurs cis to N .

As expected the non-polar side chain of (I) shows a gradual increase in temperature factors (and e.s.d.'s in positional parameters) with a minimum for $\mathrm{C}^{\alpha}[\mathrm{C}(2)]$, gradually increasing to a maximum for $\mathrm{C}^{\varepsilon}[\mathrm{C}(6)]$.
The carboxyl group $\mathrm{C}(1), \mathrm{C}(2), \mathrm{O}(1)$ and $\mathrm{O}(2)$ are coplanar with N deviating from the plane by $0.190 \AA$ (Table 3, plane 1). The atoms involved in the double bond $C(4)=C(5)$ are essentially planar $[C(3), C(4)$, $\mathrm{C}(5)$ and $\mathrm{C}(6)]$ (Table 3, plane 2).
Torsion angles representing the backbone and sidechain conformations are given in Table 4. C(3) and C(6) are trans with respect to $\mathrm{C}(4)=\mathrm{C}(5)$. The $\chi^{2}$ angle of $246 \cdot 1^{\circ}$ does not occur in any of the staggered conformations $\left(60,180,300^{\circ}\right)$ generally observed for the amino acid side chains (Lakshminarayanan, Sasisekharan \& Ramachandran, 1967). This peculiarity is attributed to the double bond $\mathrm{C}(4)=\mathrm{C}(5)$ which necessarily restricts the side-chain conformation. Table 4 also gives the torsion angles of other methionine structures: the $\alpha$ and $\beta$-forms of dl-methionine (Mathieson, 1952), L-methionine (Torii \& Itaka, 1973) and Lmethionine. HCl (Di Blasio, Pavone \& Pedone, 1977). Table 4 shows that $\chi^{2}$ is generally near $180^{\circ}$ except for (I) and for the $B$ molecule of L -methionine. For $\beta$ methionine and for L -methionine ( $A$ molecule) the

| (b) | $x$, | $\frac{1}{2}-y$, | (c) |
| $\frac{1}{2}+z-1$ | (d) | $x$, | $\frac{1}{2}-y+1$, |

$\chi^{3}$ angle shows that $\mathrm{C}^{\beta}$ and the terminal methyl $\mathrm{C}^{\varepsilon}$ are trans to each other as observed for (I). Table 4 shows that in none of the structures is the cis conformation observed (i.e. $\chi^{3}$ close to $0^{\circ}$ ).

A view of the molecule down $b$ is given in Fig. 2. The alternative Cl positions of low occupancy are given by dots and are approximately in a plane parallel to (001).

Table 5 gives the hydrogen-bond distances and angles referred to the predominant Cl position. $\mathrm{H}(1)$ and $\mathrm{H}(3)$ of $\mathrm{NH}_{3}^{+}$are hydrogen bonded to symmetryrelated $\mathrm{Cl}^{-}$ions $\left(\mathrm{Cl}\right.$ and $\left.\mathrm{Cl}^{b}\right)$ at $D \cdots A$ distances of 3.18 and $3.38 \AA$ respectively. $\mathrm{H}(2)$ of N forms a bifurcated hydrogen bond with $\mathrm{Cl}^{a}$ and $\mathrm{O}(1)^{d}$ at $D \cdots A$ distances of 3.22 and $2.95 \AA$ respectively. Table 5 shows that (for the bifurcated hydrogen bond) the distances $\mathrm{H}(2)$ to $\mathrm{Cl}^{a}$ and $\mathrm{O}(1)^{d}$ are 2.27
and $2.42 \AA$ respectively and the latter distance suggests that it is a weak interaction. The hydroxyl $O$ (2) forms a hydrogen bond with $\mathrm{Cl}^{c}$ at a distance of $2.99 \AA$.
