lactatobis( $N$-isopropyl-2-methyl-1,2-propanediamine)copper(II) L-lactate monohydrate (Ahlgren \& Hämäläinen, 1978), the Cu atom has normal $4+1$ coordination. The trigonal-bipyramidal configuration can be considered a distortion of the square-planar arrangement through movement of the two trans N atoms $[N(2)$ and $N(4)]$ within the plane containing them, Cu , and the atom at the apex of the square pyramid $[\mathrm{N}(5)]$ to positions such that the angles made with the Cu and the apical atom are about $120^{\circ}$. In this structure $\mathrm{N}(2)-\mathrm{Cu}-\mathrm{N}(5)$ is $133.8(15)^{\circ}$ and $\mathrm{N}(4)-\mathrm{Cu}-\mathrm{N}(5)$ is $127 \cdot 1(14)^{\circ}$.

Each of the five-membered Cu -diamine rings is in an unsymmetrical gauche configuration. The complex cation has approximate $C_{2}$ symmetry, the axis passing through $\mathrm{N}(5)$ and Cu . All interionic contacts are normal, the shortest being 2.93 (2) $\AA$ between $\mathrm{N}(2)$ and $\mathrm{O}(3)$.

#### Abstract

C}_{24} \mathrm{H}_{54} \mathrm{P}_{2} \mathrm{Pt}, \quad\left[\mathrm{Pt}\left(\mathrm{C}_{12} \mathrm{H}_{27} \mathrm{P}\right)_{2}\right]\), monoclinic, $P 2_{1} / n, a=8.630$ (2), $b=13.733$ (7), $c=12.049$ (6) $\AA, \beta=93.74(3)^{\circ}, Z=2, D_{m}=1.40, D_{x}=1.396 \mathrm{Mg}$ $\mathrm{m}^{-3}, \mu($ Мо $K \alpha)=5.27 \mathrm{~mm}^{-1}, \lambda($ Мо $K \alpha)=0.71069$ $\AA$. The structure was refined from 1804 observed reflections measured on a diffractometer; $R=0.046$. The $\mathrm{Pt}-\mathrm{P}$ distance is 2.249 (3) $\AA$.

Introduction. Although crystal structures of twocoordinated complexes of zerovalent Pt or Pd with phosphines have been reported (Otsuka, Yoshida, Matsumoto \& Nakatsu, 1976; Immirzi, Musco, Zambelli \& Carturan, 1975), no data on this type of 0567-7048/79/123060-03\$01.00
compound involving the bulky tri-tert-butylphosphine group were available. Therefore, a structural determination was carried out for the title compound, $\mathrm{Pt}\left[\mathrm{P}(\text { tert }-\mathrm{Bu})_{3}\right]_{2}$.

The space group was determined by photographic methods. The crystal used, which was approximately cubic with edges of 0.11 mm , was mounted on a Syntex $P 2_{1}$ automatic diffractometer. 15 automatically centred reflections were used in a least-squares refinement to give the cell constants and the orientation matrix. Two reflections ( 011 and 110 ) were measured after every 48 reflections to monitor the stability of the data collection; the intensities of these checking (c) 1979 International Union of Crystallography

reflections fluctuated within $\pm 4 \%$. Of 2534 reflections with $2 \theta<50^{\circ}, 1804$ had net intensities greater than $\sigma(I)$ and were considered to be observed. Lorentz and polarization corrections were applied to derive the structure amplitudes. No absorption correction was made, $\mu R=0.53$.

The measured density indicated that there were two molecules per unit cell and the Patterson map showed a partial image of the molecule. A least-squares refinement based on isotropic temperature factors for all non-hydrogen atoms gave an $R\left(=\sum\left|F_{o}\right|-\left|F_{\mathrm{c}} \|\right|\right.$ $\sum\left|F_{o}\right|$ ) factor of 0.08 for all observed reflections. The unobserved reflections were given zero weight in the refinement. When anisotropic temperature factors were introduced, the $R$ and $R_{w}\left\{=\left[\sum w\left(\left|F_{o}\right|-\left|F_{c}\right|\right)^{2}\right]\right.$ $\left.\left.\sum w \mid F_{o}{ }^{2}\right]^{1 / 2}\right\}$ were reduced to 0.046 and 0.055 respectively, where $w^{-1}=\left(80-F_{o}+0.0125 F_{o}^{2}\right)$. The quantity minimized was $\sum w\left(\left|F_{o}\right|-\left|F_{c}\right|\right)^{2}$. Atomic scattering factors from Cromer \& Waber (1965) with anomalous dispersion for Pt (Cromer, 1965) were used. The $R$ factor including all reflections was 0.065 . The difference Fourier map (max. 1.3 e $\AA^{-3}$ ) at this stage did not lead us to feel confident about the locations of the H atoms, which were therefore not included in the structure factor calculations. Atomic coordinates are given in Table 1.*

Discussion. The structure consists of individual molecules packed in the crystal via van der Waals forces. The molecule has a centre of symmetry on the Pt atom and, therefore, the substituents on the P atoms exist in a staggered conformation. The molecular centre of symmetry coincides with that of the unit cell. The

linear arrangement is a noteworthy structural feature when compared with $\mathrm{Pt}\left[\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{11}\right)_{3}\right]_{2}$ and $\mathrm{Pt}\left[\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)-\right.$ (tert-Bu) $)_{2}$. Both the latter two compounds have a bent $\mathrm{P}-\mathrm{Pt}-\mathrm{P}$ moiety with angles of 160.5 (2) and $177.0(1)^{\circ}$ respectively (Immirzi et al., 1975; Otsuka et al., 1976). The Pt-P bond lengths are 2.249 (3), 2.231 (4) and 2.252 (1) $\AA$ respectively for the aforementioned compounds. These data support the claim that $\mathrm{P}(\text { tert }-\mathrm{Bu})_{3}$ is a bulky phosphine ligand which has a cone angle of 182 (2) ${ }^{\circ}$ (Tolman, 1970). In contrast, the less bulky phosphines, $\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)(\text { tert }-\mathrm{Bu})_{2}$ [cone angle $170(2)^{\circ} \mathrm{J}$, in the Pt complex adopt an eclipsed conformation.

An ORTEP drawing of half the molecule is given in Fig. 1, which shows a view from a direction perpen-
dicular to the $\mathrm{P}-\mathrm{Pt}-\mathrm{P}$ moiety. Selected bond lengths and angles are given in Table 2. Values of 115.9 (10), 115.6 (10) and 116.4 (9) ${ }^{\circ}$ are found for $\angle \mathrm{PC}(11)$ $\mathrm{C}(14), \angle \mathrm{PC}(21) \mathrm{C}(22)$ and $\angle \mathrm{PC}(31) \mathrm{C}(34)$ respectively. All these angles involve a C atom pointing away from the Pt . The mean value for the remaining $\angle \mathrm{PCC}$ angles is $107.9(9)^{\circ}$.

This work was supported by the Natural Sciences and Engineering Research Council of Canada. The compound was prepared by A. B. Goel and W. O. Ogini.

Co}\left(\mathrm{C}_{12} \mathrm{H}_{10} \mathrm{~N}_{2}\right)_{2} \mathrm{Cl}\left(\mathrm{H}_{2} \mathrm{O}\right)\right] \mathrm{NO}_{3} . \mathrm{H}_{2} \mathrm{O}, \quad \mathrm{C}_{24}\) $\mathrm{H}_{22} \mathrm{ClCoN}_{4} \mathrm{O}^{+} . \mathrm{NO}_{3}^{-} \cdot \mathrm{H}_{2} \mathrm{O}, M_{r}=556 \cdot 38$, triclinic, $P \overline{1}$, $a=9.977^{(1)}, b=14.171$ (3), $c=9.185$ (1) $\AA, \alpha=$ $103.68(1), \beta=89.12(1), \gamma=98.27(1)^{\circ}, \quad V=$ 1248.4 (2) $\AA^{3}, Z=2, D_{c}=1.48 \mathrm{Mg} \mathrm{m}^{-3}$. Final $R=$ 0.051 for 1958 observed reflexions. The Co atom presents distorted octahedral coordination. The free water molecule connects the $\mathrm{NO}_{3}$ group to the Cl atom and to the coordinated water molecule through hydrogen bonds.

Introduction. The crystals were provided by the Departamento de Quimica Analitica of the University of Granada (Spain). An orange prismatic single crystal was used to collect the intensities of 3455 reflexions up to $\theta=25^{\circ}$ at 295 K on a PW 1100 fourcircle diffractometer. An $\omega / 2 \theta$ scan technique and graphite-monochromated Mo $K \alpha$ radiation ( $\lambda=$ $0.71069 \AA$ ) were used.

Two reflexions were monitored periodically and showed no crystal decomposition. The intensities were corrected for Lorentz and polarization effects and 1958 of them were considered as observed by the criterion $I$ $>2 \sigma(I)$. The absorption effects ( $\mu=0.813 \mathrm{~mm}^{-1}$ ) were not corrected. Scattering factors for neutral atoms and anomalous-dispersion corrections for Co and Cl were taken from International Tables for X-ray Crystallography (1974).

The structure was solved by MULTAN (Main, Lessinger, Woolfson, Germain \& Declercq, 1977). The best $E$ map revealed $\sim 20 \%$ of the non-hydrogen atoms. The remaining non-hydrogen atoms appeared in successive Fourier syntheses. Anisotropic full-matrix least-squares refinement with unit weights led to $R=$ $0 \cdot 060$. A difference synthesis calculated with those reflexions within $\sin \theta / \lambda<0.5 \AA^{-1}$ showed all H atoms. In order to prevent bias on $\Delta F v s F_{o}$ or $\sin \theta / \lambda$, the last steps of the refinement were carried out with weights $w$ © 1979 International Union of Crystallography
