# Caesium Lanthanum Bis(sulphate) 

By Nataša Bukovec, Venčeslav Kaučič and Ljubo Golič<br>Department of Chemistry, University Edvard Kardelj, Murnikova 6, 61000 Ljubljana, Yugoslavia

(Received 11 August 1979; accepted 11 September 1979)

#### Abstract

CsLa}\left(\mathrm{SO}_{4}\right)_{2}\), monoclinic, $P 2_{1} / n, a=$ 7.929 (1), $b=5.483(1), c=17.153$ (1) $\AA, \beta=$ $91.46(1)^{\circ}$ at $293(1) \mathrm{K}, Z=4, D_{o}=4.19, D_{c}=4.13$ $\mathrm{Mg} \mathrm{m}^{-3}, V=745.5 \AA^{3}, \mu($ Mo $K a)=11.25 \mathrm{~mm}^{-1}$. The La atom is nine coordinated by O atoms in the form of an irregular polyhedron. The polyhedra together with the S atoms form a layer-like structure parallel to the [101] diagonal. The Cs atoms, which lie between the layers, have a coordination number of thirteen.

Introduction. There are two different structure modifications of compounds $\mathrm{CsLn}\left(\mathrm{SO}_{4}\right)_{2}(\mathrm{Ln}=\mathrm{La}, \mathrm{Pr})$, which can be prepared by heating $\mathrm{CsLn}\left(\mathrm{SO}_{4}\right)_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}$ with a 4.5 M solution of $\mathrm{H}_{2} \mathrm{SO}_{4}$ in a sealed tube at 573 K. The structure of $\mathrm{CsPr}\left(\mathrm{SO}_{4}\right)_{2}$ has been solved (Bukovec, Golič, Bukovec \& Siftar, 1978). Both $\mathrm{CsPr}\left(\mathrm{SO}_{4}\right)_{2}$ and $\mathrm{CsLa}\left(\mathrm{SO}_{4}\right)_{2}$ crystallize as thin plates.

Cell dimensions of $\mathrm{CsLa}\left(\mathrm{SO}_{4}\right)_{2}$ were derived by least squares from the positions of 30 high-angle reflections, collected on an Enraf-Nonius CAD-4 automatic diffractometer equipped with a graphite monochromator and using Mo $K \alpha$ radiation. Intensities were recorded with the $\omega-2 \theta$ scan. The whole sphere of reflections (4335 in all) in the range $1.5 \leq \theta \leq 30.0^{\circ}$ was measured. The symmetry-related reflections were averaged (mean discrepancy on $I=5.6 \%$ ) to yield 2141 independent reflections of which 1973 with $I_{o} \geq$ $3 \sigma\left(I_{o}\right)$ (from counting statistics) were considered observed and used for the analysis. The data were corrected for Lorentz and polarization effects. An absorption correction based on the equations of the crystal faces was also applied to all the reflections.

The structure was solved with MULTAN (Main, Hull, Lessinger, Germain, Declercq \& Woolfson, 1978) to locate the La and Cs atoms and electron density maps to locate the remaining atoms. Refinement of the positional and isotropic thermal parameters gave $R=$ $0 \cdot 073$. The structure was then refined with anisotropic temperature factors for all atoms to $R_{1}=\sum| | F_{o} \mid-$ 0567-7408/80/010129-02\$01.00
$\left|F_{c}\right|\left|\sum\right| F_{o} \mid=0.066$, and $R_{2}=\left[\sum w\left(F_{o}-F_{c}\right)^{2} /\right.$ $\left.\sum w F_{o}^{2}\right]^{1 / 2}=0.073$. The weighting function was determined empirically [weight $\left(F_{o}\right)=w F \times w S$ ]: $F_{o}<30$ : $w F=\left(F_{o} / 30\right)^{1 \cdot 0} ; F_{o}>60: w F=\left(60 / F_{o}\right)^{1 \cdot 5} ; 30 \leq F_{o} \leq$ 60: wF = 1.0; $\sin \theta<0.35: w S=(\sin \theta / 0 \cdot 35)^{2} ; \sin \theta>$ 0.45: $w S=(0.45 / \sin \theta)^{2} ; 0.35 \leq \sin \theta \leq 0.45: w S=$ 1.0 .

Scattering factors for neutral $\mathrm{Cs}, \mathrm{La}, \mathrm{S}$ and O (Cromer \& Mann, 1968) with anomalous-scattering coefficients $f^{\prime}$ and $f^{\prime \prime}$ (Cromer \& Liberman, 1970) were used. No extinction correction was applied.*

Discussion. The final atomic coordinates are listed in Table 1. The La atom is coordinated to nine O atoms in the form of an irregular polyhedron. Interatomic distances and angles are given in Table 2. There are only small differences between $\mathrm{S}-\mathrm{O}$ distances in the $S(1)$ sulphate group (Table 3). However, $S(2)-O(7)$ in

the $\mathbf{S}(2)$ sulphate group is rather longer than the others because $\mathrm{O}(7)$ is a bridging atom between two La atoms. The $\mathrm{La}-\mathrm{O}(7)-\mathrm{La}$ angle is $134.2(3)^{\circ}$ and $\mathrm{O}(7)-\mathrm{La}$ bond distances are 2.739 (8) and 2.801 (8) $\AA$. Smaller angles $\mathrm{O}(1)-\mathrm{S}(1)-\mathrm{O}(3), \mathrm{O}(5)-\mathrm{S}(2)-\mathrm{O}(7)$ and $\mathrm{O}(7)-$ $\mathrm{S}(2)-\mathrm{O}(8)$ result from the bonding of O atoms to the

Fig. 1. A view of the unit cell.

Fig. 2. The coordination polyhedron of caesium.
same La atoms. Thus each sulphate group is bonded to three La atoms. The sulphate groups join La polyhedra into infinite layers parallel to the [101] diagonal (Fig. 1).

The Cs atoms lie between the layers and are coordinated with thirteen O atoms (Fig. 2). The coordination polyhedron around Cs is in the form of two parallel sixfold rings; one of them is centred. This can be compared with the Cs polyhedron in CsPr $\left(\mathrm{SO}_{4}\right)_{2}$, where both sixfold rings are centred and the coordination number is fourteen.

Financial support by the Research Council of Slovenia is gratefully acknowledged.
