the $\left[\mathrm{PS}_{4}\right]$ tetrahedra is $3.32 \AA$, the $\mathrm{P}-\mathrm{S}$ distances ranging between 2.03 and $2.04 \AA$. Such $\left[\mathrm{PS}_{4}\right]$ tetrahedra occur in various thiophosphates, e.g. in $\mathrm{GaPS}_{4}, d_{\mathrm{s}-\mathrm{s}}=3.34, d_{\mathrm{P}-\mathrm{s}}=2.05$ (Buck \& Carpentier, 1973); $\mathrm{InPS}_{4}, d_{\mathrm{S}-\mathrm{s}}=3.36, d_{\mathrm{P}-\mathrm{S}}=2.04$ (Diehl \& Carpentier, 1978); $\mathrm{Cd}_{13} \mathrm{P}_{4} \mathrm{~S}_{22} \mathrm{I}_{2}, d_{\mathrm{s}-\mathrm{s}}=3.35, d_{\mathrm{P}-\mathrm{s}}=$ $2.05 \AA$ (Bubenzer, Nitsche \& Grieshaber, 1976).

From a formal, electrochemical point of view, the compound therefore can be envisaged as containing two cations $\mathrm{Ta}^{5+}$ and $\mathrm{P}^{5+}(1: 1)$ and two anions, namely $[\mathrm{S}-\mathrm{S}]^{2-}$ and $\mathrm{S}^{2-}(1: 4)$, resulting in the formula $\mathrm{Ta}\left[\mathrm{PS}_{4} \mid \mathrm{S}_{2}\right]$.

Fig. 2 is a projection along [00ī], Fig. 3 a stereoscopic drawing of the unit-cell contents. The $\left[\mathrm{Ta}_{2} \mathrm{~S}_{12}\right.$ ] units, linked by the $\left[\mathrm{PS}_{4}\right]$ tetrahedra, form endless chains, spiralling around the $4_{1}$ and $4_{3}$ axes. Spiral chains around adjacent screw axes of opposite sense do not interfere with each other and have no common units. Spiral chains around adjacent screw axes of the same sense are interconnected by common $\left[\mathrm{Ta}_{2} \mathrm{~S}_{12}\right]$ units.

Similar metal chalcogen units, $\left[\mathrm{Nb}_{2} \mathrm{Se}_{12}\right]$, are found in $\mathrm{Nb}_{2} \mathrm{Se}_{9}$ (Meerschaut, Guémas, Berger \& Rouxel, 1979). However, in this compound they are crosslinked by common Se atoms into parallel chains. In $\mathrm{ZrSe}_{3}$ on the other hand (Krönert \& Plieth, 1965) and in $\mathrm{NbSe}_{3}$ (Meerschaut \& Rouxel, 1975) the bicapped triangularprismatic arrangement of eight Se around each metal is still present, but these prisms have no common rectangular prism faces. Instead they are connected via common triangular endfaces into infinite chains.

A similar arrangement of metal-metal and (perpendicular) $[\mathrm{S}-\mathrm{S}]^{2-}$ pairs as in $\mathrm{Ta}\left[\mathrm{PS}_{4} \mid \mathrm{S}_{2}\right]$ is present in $\mathrm{Nb}_{2} \mathrm{~S}_{2} \mathrm{Cl}_{2}$ (von Schnering \& Beckmann, 1966) and in $\mathrm{VS}_{4}$ (Allmann, Baumann, Kutoglu \& Rösch, 1964).

Another interesting feature of the $\mathrm{Ta}\left[\mathrm{PS}_{4} \mid \mathrm{S}_{2}\right]$ structure is the existence of rather large channels
extending along the fourfold screw axes (Fig. 3). It appears probable that foreign atoms or small molecules can be inserted into and move in these channels, the free diameter of which is about $4.65 \AA$.

One of us (SF) is indebted to K. Scheunemann for introducing him to XRAY 76 and for help in interpreting the Patterson maps. All calculations were carried out on the Univac 1100/81 computer of the Rechenzentrum der Universität Freiburg.

# The Structure of Pentaindium Tetrasulfide 

By Tommy Wadsten, Lars Arnberg and Jan-Eric Berg<br>Departments of Inorganic and Structural Chemistry, Arrhenius Laboratory, University of Stockholm, $S$-106 91 Stockholm, Sweden

(Received 9 October 1979; accepted 22 May 1980)

#### Abstract

The structure of the new compound $\operatorname{In}_{5} \mathrm{~S}_{4}$ has been determined by direct methods using single-crystal

X-ray diffractometer data and refined to $R=0.046$. The symmetry is Pa3 and the cell edge is 12.340 (10) $\AA$. There are eight formula units in the cell. The structure consists of a three-dimensional network of corner-
© 1980 International Union of Crystallography
sharing $\operatorname{In}_{2} \mathrm{~S}_{3}$ tetrahedra with one of the In atoms at the center of the tetrahedron. The other In atom is the common corner of four tetrahedra; these aggregates form major building units of the structure. The coordination around In is thus either four In atoms or one In (at $2.77 \AA$ ) and three S (at $2.54 \AA$ ). Each S coordinates three In atoms. There are no $\mathbf{S}-\mathbf{S}$ bonds.

## Introduction

In the binary system $\operatorname{In}-\mathrm{S}$ the existence of several phases has been proposed. During extensive work in recent years only a few have been proved to be real. They are InS, reported by Schubert, Dörre \& Günzel (1954), $\mathrm{In}_{6} \mathrm{~S}_{7}$, investigated by Hogg \& Duffin (1967), and three polymorphic forms of $\operatorname{In}_{2} \mathrm{~S}_{3}$. The $\alpha$ type was studied by Hahn \& Klingler (1949), the $\beta$ type by Steigmann, Sutherland \& Goodyear (1965) and the $\gamma$ type by Diehl, Carpentier \& Nitsche (1976).

These compounds can be prepared by direct combination of the elements at elevated temperatures. The successful application of molten tin as a solvent in the synthesis of silicon monophosphide (Wadsten, 1975) and of gallium chalcogenides (Wadsten, 1977) suggested its use also in this binary system.

By heating mixtures of In and S with excess Sn in evacuated silica tubes the new compound $\mathrm{In}_{5} \mathrm{~S}_{4}$ was obtained in high yield. The crystals are red and transparent and sometimes up to a few mm in length. The preparation procedure will be described in a separate paper by Wadsten (1980).

The S content of the purified material was determined by gas chromatographic techniques according to Kirsten (1961). The value observed was $18.5 \pm 2 \%$ by weight and the calculated value is $18.3 \%$. No tin impurity could be observed by X-ray fluorescence. The detection limit with this technique is of the order of 100 p.p.m.

## Experimental

The lattice constant was obtained from powder data (Guinier-Hägg camera) using $\mathrm{Cu} K \alpha$ radiation ( $\lambda=$ $1.5418 \AA)$ and $\mathrm{KCl}(a=6.2930 \AA)$ as an internal standard.

A preliminary investigation was performed with Weissenberg methods, and a suitable crystal was selected with the approximate volume $0.0007 \mathrm{~mm}^{3}$.

Crystal data are: space group Pa3 (No. 205), $a=$ $12 \cdot 340$ (10) $\AA, V=1884 \AA^{3}, Z=8, D_{m}=4.87, D_{x}=$ $4.95 \mathrm{Mg} \mathrm{m}^{-3}, \mu(\mathrm{Cu} K)=91.29 \mathrm{~mm}^{-1}$.

The reflexion intensities were measured on a Philips PW 1100 diffractometer using graphite monochromatized $\mathrm{Cu} K \alpha$ radiation. Diffraction intensities within the $+h$ hemisphere of reciprocal space were
collected out to $2 \theta=134^{\circ}$ with the $\theta-2 \theta$ scan technique. Of the 1937 reflexions measured, 560 were unique. All unique reflexions were used in the subsequent refinements. Lorentz, polarization and spherical absorption corrections were applied.

## Structure determination and refinement

An $E$ map computed from 107 reflexions with $|E| \geq$ $1 \cdot 2$ displayed all In atoms as prominent peaks. The remaining atoms were placed from a difference $F$ map. The structural parameters, assuming first isotropic and then anisotropic thermal vibrations, were refined by the full-matrix least-squares method, using unit weights, to a final $R$ value of 0.046 .* Direct-method, Fourier and least-squares programs were those included in the SHELX system (Sheldrick, 1976). The complex atomic scattering factors for In and S were those listed in International Tables for X-ray Crystallography (1974) for neutral atoms. Table 1 comprises the atomic positional parameters.

## Description of the structure

The structure analysis of this compound has revealed a new structure type which can be visualized as a three-dimensional network of corner-sharing $\mathrm{In}_{2} \mathrm{~S}_{3}$ tetrahedra.

The $\operatorname{In}(1)$ and $\operatorname{In}(3)$ atoms are each surrounded by one $\operatorname{In}(2)$ and three S atoms. The coordination polyhedra around $\operatorname{In}(1)$ and $\operatorname{In}(3)$ are somewhat distorted tetrahedra since the In-In contacts are longer than the In-S. In Table 2 the interatomic distances within these tetrahedra are collected.

One $\operatorname{In}(1)$ - and three $\operatorname{In}(3)$-centered tetrahedra have a common $\operatorname{In}(2)$ corner and thus form what might be called a tetra-tetrahedron, with composition $\operatorname{In}_{5} \mathrm{~S}_{12}$. In this way all In atoms achieve tetrahedral coordination

Fig. 1. The atomic arrangement in the tetra-tetrahedra. In (a) the $\operatorname{In}(1)$ and $\operatorname{In}(3)$ atoms are omitted, and in (b) the 12 S atoms are omitted.
(Fig. 1). The $\operatorname{In}(1)$ and the three $\operatorname{In}(3)$ atoms in the tetra-tetrahedron form a fairly regular tetrahedron around $\operatorname{In}(2)$. Bond angles and distances are given in Table 2.

As can be seen from Fig. 1, six S atoms, every second $\mathrm{S}(1 A)$ and $\mathrm{S}(1 B)$, form a zig-zag, six-membered ring with a departure from a least-squares plane of $\pm 0.064$ (1) $\AA$. The distance between each atom is the same, viz. $3.972(5) \AA$. This almost planar $\mathrm{S}_{6}$ ring is common to two tetra-tetrahedra, and in this way a double tetra-tetrahedron is formed (Fig. 2). There are eight $\mathrm{In}_{2} \mathrm{~S}_{3}$ tetrahedra in this arrangement, and the composition is $\operatorname{In}_{10} \mathrm{~S}_{18}$. The sequence of $\operatorname{In}(1)$ and $\operatorname{In}(2)$ atoms, $\operatorname{In}(1)-\operatorname{In}(2)-\operatorname{In}(2)-\operatorname{In}(1)$, is directed along the body diagonals of the cubic cell. The void formed between the two tetra-tetrahedra has two $\operatorname{In}(2)$ atoms at a distance of $2.14 \AA$ and $\operatorname{six} \operatorname{In}(3)$ atoms at a distance of $2.98 \AA$ from its center. The double tetra-tetrahedra are centered at the sites of a close-packed cubic lattice (Fig. 3), whose stereoscopic equivalent is shown in Fig.

Fig. 2. The arrangement of eight $\operatorname{In}_{2} S_{3}$ tetrahedra forming the double tetra-tetrahedron. The arrows indicate the hexagonal $S_{6}$ ring.

Fig. 3. Orientation and center of gravity of the double tetratetrahedra, here represented by the $\operatorname{In}(1)-\operatorname{In}(2)-\operatorname{In}(2)-\ln (1)$ sequence, in one elementary cell. One of these clusters is centrosymmetrical.

Fig. 4. Stereoscopic representation of the $\operatorname{In}(1)-\operatorname{In}(2)-\operatorname{In}(2)-\operatorname{In}(1)$ arrangements in the cubic $\operatorname{In}_{5} \mathrm{~S}_{4}$ structure.

4, and each double tetra-tetrahedron will thus be surrounded by twelve others. They are linked together by the $S(1)$ atoms common to one $\ln (1)$ and two $\operatorname{In}(2)$ tetrahedra. The $S(2)$ atoms are shared by three different double tetra-tetrahedra.

In this way all S atoms achieve coordination to three In atoms as nearest neighbors.

The composition is now $\operatorname{In}_{40} \mathrm{~S}_{32}$, which corresponds to the unit-cell content.

## Structural relationships

The In atom at the center of the $\mathrm{In}_{2} \mathrm{~S}_{3}$ tetrahedron has an environment of three $S$ and one In atom.

A similar coordination is found among other combinations of elements from the same groups, for instance GaS (Hahn \& Frank, 1955). However, the building units in the layer structure of GaS are $\mathrm{S}_{6}$ prisms with two Ga atoms inside.

Mixed tetrahedral coordination is also exhibited by 1:1 combinations of elements from the Groups IV and V such as SiAs (Wadsten, 1965) and SiP (Wadsten, 1975). The building units of these layer compounds are $\mathrm{As}_{6}$ or $\mathrm{P}_{6}$ octahedra surrounding two Si atoms.

The compound InS (Schubert et al., 1954) can also be included as an example of mixed tetrahedral environment for the In atoms, but the structure can be visualized as being built up of corner-sharing $\operatorname{In}_{2} \mathrm{~S}_{6}$ octahedra.

# Sulphides with the $\mathbf{G d F e O}_{\mathbf{3}}$ Structure 

By R. Lelieveld and D. J. W. IJdo<br>Gorlaeus Laboratories, Section of Solid State Chemistry, University of Leiden, PO Box 9502, 2300 RA Leiden, The Netherlands

(Received 23 March 1979; accepted 7 May 1980)

#### Abstract

$\mathrm{CaZrS}_{3}, \mathrm{SrZrS}_{3}, \mathrm{BaZrS}_{3}, \mathrm{BaUS}_{3}, \mathrm{CaHfS}_{3}, \mathrm{BaHfS}_{3}$, $\mathrm{EuZrS}_{3}$ and $\mathrm{EuHfS}_{3}$ have been found to have the $\mathrm{GdFeO}_{3}\left(\mathrm{CaTiO}_{3}\right)$ structure, Pnma, with $Z=4$. For the first four compounds, atomic positional parameters have been determined by neutron diffraction powder methods. [ $R_{w}$ values were $8.00,7.51,8.14$ and 8.49 respectively.]

## Introduction

We have investigated the crystal structures of $A B S_{3}$ type compounds with $A=\mathrm{Ca}, \mathrm{Sr}, \mathrm{Ba}$ and Eu , and $B=$ $\mathrm{Zr}, \mathrm{Hf}$ and U . This is part of a research programme on the structural relations of compounds $A B X_{3}$, where $A$ represents an alkaline or an alkaline-earth metal, $B$ a transition metal and $X$ a halogen or S (van Loon \&

Verschoor, 1973; van Loon, 1974; Crama, Maaskant \& Verschoor, 1978; Lelieveld \& IJdo, 1978).

Single crystals of the $A B \mathrm{~S}_{3}$ compounds were not available, so we decided to use the neutron powder-profile-refinement technique (Rietveld, 1969) in order to obtain precise structural information for the Zr and U compounds. The ionic radii for Zr and Hf for six-coordination are 0.72 and $0.71 \AA$ respectively; hence, the same structures for $A \mathrm{ZrS}_{3}$ and $A \mathrm{HfS}_{3}$ can be expected. Moreover, for routine neutron powderdiffraction experiments samples of about 30 g are needed, so we limited ourselves to the Zr and U compounds. Neutron diffraction for Eu compounds is not useful because of the high absorption of Eu.

Hahn \& Mutschke (1956) prepared $\mathrm{BaZrS}_{3}$ and produced an X-ray powder diagram, which they indexed as a tetragonal deformed perovskite; they were unable to prepare $\mathrm{SrZrS}_{3}$ and $\mathrm{CaZrS}_{3}$. Clearfield (1963) published the X-ray powder diagrams of © 1980 International Union of Crystallography
