# Redetermination of the Structure of Putrescine Dihydrochloride 

By K. Chandrasekhar and Vasantha Pattabhi<br>Department of Crystallography and Biophysics,* University of Madras, Guindy Campus, Madras-600025, India

(Received 13 May 1980; accepted 9 June 1980)

Abstract. $\mathrm{C}_{4} \mathrm{H}_{14} \mathrm{~N}_{2}^{2+} .2 \mathrm{Cl}^{-}, M_{r}=161 \cdot 1$, monoclinic, $P 2_{1} / c, a=4.589$ (2),$b=8.349$ (3), $c=10.729$ (4) $\AA$, $\beta=92.54(2)^{\circ}, V=410.7 \AA^{3}, Z=2, D_{m}=1.31(1)$, $D_{c}=1.305 \mathrm{Mg} \mathrm{m}{ }^{-3}, \mu(\mathrm{Cu} K \alpha)=6.44 \mathrm{~mm}^{-1} ; R=$ 0.064 . The amino groups are protonated and $\mathrm{N}-\mathrm{H} \cdots \mathrm{Cl}$ hydrogen bonds are observed.

Introduction. Putrescine, derived from the decarboxylation of ornithine, is one of the most active of a series of polyamines that are essential growth factors for a number of micro-organisms. The structure of its dihydrochloride (PDH) has been investigated by Ashida \& Hirokawa (1963b) with 190 visually estimated intensities. They have not corrected for absorption, have quoted no e.s.d.'s except in the cell parameters and have refined isotropically only the zonal reflections $h 0 l$ and $h k 0$. In view of the marked biological importance of putrescine, we have redetermined the structure of PDH as part of a continuing programme in our laboratory on the structure and conformation of polyamines.

681 independent non-zero intensities were collected by counter methods with a $\theta-2 \theta$ scan and Ni-filtered $\mathrm{Cu} K a$ radiation $(\lambda=1.5418 \AA)$. The data were corrected for Lorentz and polarization effects, and for absorption (North, Phillips \& Mathews, 1966).

The position of Cl was determined from a Patterson map ( $R=0.403$ ) and a Cl-phased difference synthesis revealed the other non-hydrogen atoms ( $R=0 \cdot 187$ ). Refinement by block-diagonal least-squares techniques (Shiono, 1968) with unit weights for all reflections reduced $R$ to 0.088 . The H atoms were then located from a difference map and assigned the isotropic temperature factors of the atoms to which they are attached. Full-matrix least-squares refinement (Gantzel, Sparks \& Trueblood, 1961) with anisotropic thermal parameters for the non-hydrogen atoms and

$$

Hughes's (1941) weighting ( $1 / \sqrt{ } w=1$ for $F_{o}<28$, and $F_{0} / 28$ otherwise) led to a final $R$ of 0.064 .

The H -atom parameters were not refined. Scattering factors were taken from International Tables for $X$-ray Crystallography' (1962) and an anomalous-dispersion correction was applied for Cl (Cromer \& Liberman, 1970). A final difference map showed no extraneous peaks.

The final atomic positions and thermal parameters are given in Table $1, \dagger$ bond lengths and angles in Fig. 1.

Discussion. The gross features of the structure are in accord with those reported by Ashida \& Hirokawa (1963b). A comparison of the bond lengths and angles with those in some relevant studies is presented in Table 2. The two N atoms are displaced from the plane of the four C atoms by only $\pm 0.022$ (4) $\AA$, so that the entire charged molecule of putrescine is zigzag planar making angles of $25.8,83.9$ and $64.5^{\circ}$ with the $a b, b c$ and $c a$ planes respectively. The amino groups are protonated and the three H atoms are staggered when viewed along the $\mathrm{C}-\mathrm{N}$ bond.

A projection of the crystal structure down a is shown in Fig. 2 and the short $\mathrm{N} \cdots \mathrm{Cl}$ approaches are in Table 3. Donohue (1952) has indicated that in crystals containing $\mathrm{N}^{+} \mathrm{H}_{3}$ groups and $\mathrm{Cl}^{-}$ions, the occurrence

* Spermine in this structure has a $t-t-t-g-t-t-t-g-t-l-t$ conformation, while all the others form normal extended chains.
of four short $\mathrm{N} \cdots \mathrm{Cl}$ distances is a common feature; three may be ascribed to hydrogen-bond formation, and the fourth, a short contact directed approximately along the extension of the $\mathrm{C}-\mathrm{N}$ bond, to packing requirements due to the size of the $\mathrm{Cl}^{-}$ions. In PDH three of the $\mathrm{C}-\mathrm{N} \cdots \mathrm{Cl}$ angles (Table 3) are close to the tetrahedral value to allow normal hydrogen-bond formation while the $\mathrm{C}-\mathrm{N} \cdots \mathrm{Cl}(1)(d)$ angle of $163.4(4)^{\circ}$ is too high to merit similar consideration. The $\mathrm{N}(1)-\mathrm{H} 1(\mathrm{~N} 1) \cdots \mathrm{Cl}(1)(d)$ angle of $84.7^{\circ}$ also seems too low for $\mathrm{N}(1) \cdots \mathrm{Cl}(1)(d)$ to be considered a bifurcated hydrogen bond.

The molecule forms an infinite layered structure perpendicular to a. The putrescinium ions are held in sheets by van der Waals forces; the Cl atoms form rows between the sheets and are joined to the protonated amino groups through hydrogen bonds.

The hydrogen-bonding scheme is different from that in spermine tetrahydrochloride (Giglio, Liquori, Puliti \& Ripamonti, 1966a) where the four short $\mathrm{N} \cdots \mathrm{Cl}$ distances can be considered in pairs, two being normal hydrogen bonds and the other two possibly bifurcated hydrogen bonds. Further, the arrangement of $\mathrm{Cl}^{-}$ions surrounding each N in PDH is remarkably similar to

Woo, Seeman \& Rich (1979) find a gauche-trans conformation for putrescine in the diphosphate. They point out that while in such a conformation the putrescine molecule can fit across the major groove of both A-RNA and ApU-RNA but cannot bridge the DNA helix, in the all-trans conformation it can bridge the DNA double helix as well as RNA helices, forming two hydrogen bonds in each case. Indeed, we do find an all-trans conformation for putrescine in PDH. In this context, the distances between the eight $\mathrm{Cl}^{-}$ions surrounding each putrescine molecule may be of interest and these are listed in Table 4.

The authors thank Professor R. Srinivasan for valuable discussions. One of the authors (KC) acknowledges financial assistance from the University Grants Commission, New Delhi, India.

# Bis(4-nitrophenyl) Ketone 

By Giacomo Chiari,* Hellen C. R. Taylor, Frank R. Fronczek and George R. Newkome Department of Chemistry, Louisiana State University, Baton Rouge, Louisiana 70803, USA

(Received 13 March 1980; accepted 10 June 1980)

#### Abstract

C}_{13} \mathrm{H}_{8} \mathrm{~N}_{2} \mathrm{O}_{5}\), triclinic, $P \overline{1}, a=7.323$ (2), $b=$ 12.634 (4) , $c=13.301$ (3) $\AA, \alpha=89.37$ (2),$~ \beta=$ 86.75 (2), $\gamma=87.09(3)^{\circ}, Z=4, d_{c}=1.463, d_{m}=$ $1.46 \mathrm{Mg} \mathrm{m}{ }^{-3} . R=0.037$ for 1385 observations measured by diffractometer. The two independent molecules of the asymmetric unit exist in approximate $C_{2}$ conformations, with the aromatic rings tipped an average of $28^{\circ}$ out of the plane of the ketone unit. The nitro substituents are essentially coplanar with the aromatic rings. The formula given above has been definitively determined by crystallographic tests as well as other physical and spectral techniques.

Introduction. The recent discovery of a facile means of decarbonylation (Newkome \& Taylor, 1979) led us to attempt the synthesis of cyclobutal $1,2-b: 4,3-b^{\prime}$ ldipyridine (I) from 1,8-diazafluorenone (II) by treatment with sodium hydride in xylene.

Rather than the anticipated compound, chemical decarbonylation produced predominantly an uncharacterized black material. Also isolated from the reaction mixture was a minute quantity of pale-yellow needles
