(Received 16 April 1980; accepted 28 July 1980)

#### Abstract

Crystals of the title compound are tetragonal, space group $I 4_{1} / a, Z=16$, with $a=16.857(9), c=$ 36.076 (21) $\AA .1439$ independent reflections above background have been measured on a diffractometer and refined to $R=0.069$. The Ni atom in the discrete cations has a distorted octahedral environment being bonded to two N atoms of ethylenediamine [ $2 \cdot 162(13), 2 \cdot 096(14) \AA$ ] and four $N$ atoms of the macrocycle $\quad[2 \cdot 164(12), \quad 2 \cdot 013(11), \quad 2 \cdot 158(12)$, $2 \cdot 133(12) \AA]$. The macrocycle, which is planar in other complexes, is folded to allow the ethylenediamine to coordinate to the metal in a bidentate fashion. These $\mathrm{Ni}-\mathrm{N}$ (macrocycle) bond lengths are on average $0.07 \AA$ longer than those observed in similar complexes where the - macrocycle is planar. There are four independent perchlorate anions in the asymmetric unit, three of which are disordered.

## Introduction

The condensation of 2,6-pyridinediyl diacetate with $3,3^{\prime}$-diaminodipropylamine in the presence of $\mathrm{Ni}^{1 \mathrm{II}}$ salts produces the macrocyclic complex $\left[\mathrm{Ni} L^{1}\right]^{2+}$ which was first isolated as the perchlorate salt (Curry \& Busch, 1964). Reduction of $\left[\mathrm{Ni} L^{1}\right]^{2+}$ under mild conditions gave $\left[\mathrm{Ni} L^{2}\right]^{2+}$ (Karn \& Busch, 1969). Two forms of the complex were prepared, a red $\beta$ form and a yellow $\alpha$ form. These have been characterized by single-crystal structure determinations as being respectively a meso isomer in which the methyl groups are on the same side of the ring (Drew \& Hollis, 1980a) and a racemic form in which the methyl groups are on opposite sides of the ring (Dewar \& Fleischer, 1969). In both structures, the macrocycle $L^{2}$ forms a planar girdle around the metal atom with the $\mathrm{NiN}_{4}$ atoms planar within $0.11 \AA$. The structure of $\beta$ - $\left[\mathrm{Ni} L^{2}\left(\mathrm{NO}_{2}\right)_{2}\right] \cdot \frac{1}{2} \mathrm{H}_{2} \mathrm{O}$ has also been determined (Drew \& Hollis, 1980b) and once more the macrocycle forms a planar girdle around the Ni atom. However, this time the metal is six-coordinate, being

[^0]0567-7408/80/112629-04\$01.00
bonded to two nitrite ions (one through nitrogen and the other through oxygen) in axial positions.

Karn \& Busch (1969) also prepared a series of complexes of general formula $\left[\mathrm{Ni} L^{2} X_{2}\right.$ ], with $X$ a unidentate ligand such as $\mathrm{Cl}^{-}, \mathrm{Br}^{-}, \mathrm{I}^{-}, \mathrm{HCOO}^{-}, \mathrm{N}_{3}^{-}$, $\mathrm{OH}_{2}, \mathrm{NH}_{3}$, and these presumably have octahedral structures equivalent to that observed in the dinitrite complex. Of particular interest was another complex, $\left[\mathrm{Ni} L^{2}(\mathrm{en})\right]^{2+}$, en $=$ ethylenediamine, as in this complex the macrocycle $L^{2}$ must fold in order to allow the ethylenediamine ligand to coordinate to the Ni atom in the usual bidentate manner. Accordingly, we have prepared this complex, following the published method, and report here its crystal and molecular structure.

## Experimental

## Crystal data

$\left[\mathrm{Ni}\left(\mathrm{C}_{2} \mathrm{H}_{8} \mathrm{~N}_{2}\right)\left(\mathrm{C}_{15} \mathrm{H}_{26} \mathrm{~N}_{4}\right)\right]\left(\mathrm{ClO}_{4}\right)_{2}, \quad \mathrm{C}_{17} \mathrm{H}_{34} \mathrm{~N}_{6} \mathrm{Ni}^{2+}$. $2 \mathrm{ClO}_{4}^{-}, M_{r}=579.9$, tetragonal, $a=16.857$ (9), $c=36.076$ (21) $\AA, U=10251.3 \AA^{3}, Z=16, d_{m}=$ $1.57(2), d_{c}=1.50 \mathrm{Mg} \mathrm{m}^{-3}, F(000)=5056, \lambda(\mathrm{Mo} \mathrm{K} \alpha)$ $=0.7107 \AA, \mu=1.00 \mathrm{~mm}^{-1}$. Space group $I 4_{1} / a$ from the systematic absences $h k l, h+k+l=2 n+1, h k 0$, $h=2 n+1,00 l, l \neq 4 n$.

A crystal of approximate size $0.5 \times 0.4 \times 0.6 \mathrm{~mm}$ was mounted with the $c$ axis parallel to the instrument axis of a General Electric XRD5 diffractometer which was used to measure diffraction intensities, by a stationary-crystal-stationary-counter method using 10 s counts, and cell dimensions, by the least-squares
© 1980 International Union of Crystallography
refinement of some 15 high-angle data. The apparatus was equipped with a manual goniostat, scintillation counter and pulse-height discriminator. Several standard reflections monitored during the course of the experiment showed no significant change in intensity. 2390 independent reflections were measured for $2 \theta<$ $40^{\circ}$ of which 1441 with $I>2 \sigma(I)$ were used in the subsequent refinement. No absorption or extinction corrections were applied.

## Structure determination

The positions of the Ni atoms were obtained from the Patterson map and those of the remaining atoms in

the cation from Fourier maps. These were four independent Cl atoms in positions $16(f), 4(a), 8(e)$ and $4(b)$. Of these, only $\mathrm{Cl}(2)$ in $4(a)$ gave rise to an ordered perchlorate. For $\mathrm{Cl}(1)$, we refined two tetrahedra of O atoms with one shared atom, $\mathrm{O}(11)$, with population parameters 0.75 and 0.25 . The electron density around $\mathrm{Cl}(3)$ was very complicated. $\mathrm{Cl}(3)$ is on a twofold axis and we included two tetrahedra both containing $O(31)$ and $\mathrm{O}\left(31^{\text {III }}\right)$ and two other atoms. Attempts to split $\mathrm{O}(31)$ into two in order to obtain two independent ideal tetrahedra were not successful, presumably because of complications introduced by the twofold axis. For $\mathrm{Cl}(4)$ two tetrahedra were invoked, each described by two O atoms given occupancy factors of $0 \cdot 5$. Details of these proposed tetrahedra are given in the Supplementary Publication.* This model may not represent

the complete picture of the disorder, but we made innumerable attempts to explain the electron density around these Cl atoms and we consider our explanation to be as valid as any other.

For the cation, H atoms were introduced in tetrahedral or trigonal positions where appropriate. Their positional parameters were fixed but their thermal parameters were allowed to refine, which they did to convergence at reasonable values. Methyl H atoms were searched for by refining rigid groups; only those on $\mathrm{C}(21)$ were located and refined successfully. The final $R$ value obtained by refining non-hydrogen atoms anisotropically was 0.069 . Calculations were carried out on the CDC 7600 computer at the University of Manchester Computer Centre using SHELX 76 (Sheldrick, 1976). Scattering factors and dispersion corrections were taken from International Tables for $X$-ray Crystallography (1974). In the final cycle of refinement all shifts were less than $0.05 \sigma$. The difference Fourier map showed no significant peaks and the zero-weighted reflections gave no serious discrepancies. The final positions and molecular dimensions are given in Tables 1 and 2.*

## Discussion

The structure of the cation is shown in Fig. 1. There are no contacts between the cation and the anions shorter than the sum of the van der Waals radii. The cation has no imposed symmetry. As expected, the Ni atom is bonded to the four N atoms of the macrocycle $L^{2}$ together with the two N atoms of the ethylenediamine ligand. The macrocycle $L^{2}$ is folded such that while Ni ,

[^1]$N(3), N(6), N(9)$ are coplanar (maximum deviation of an atom from the plane $<0.01 \AA$ ), the remaining donor atom $\mathrm{N}(13)$ is $2 \cdot 11 \AA$ from this plane. The $\mathrm{Ni}-\mathrm{N}(3)$, $\mathrm{N}(6), \mathrm{N}(9)$ bond lengths are $2 \cdot 164(12), 2 \cdot 013$ (11), 2.158 (12) $\AA$, on average about $0.07 \AA$ longer than those observed in the six-coordinate complex [ $\mathrm{NiL}^{2}\left(\mathrm{NO}_{2}\right)(\mathrm{ONO})$ ] (Drew \& Hollis, 1980b).

The folding of the macrocycle is described by the torsion angles, Table 3, which are compared with those found in the square-planar $\left[\mathrm{Ni} L^{2}\right]^{2+}$ complex; these latter are in fact very similar to those found in [ $\mathrm{Ni} L^{2}\left(\mathrm{NO}_{2}\right)(\mathrm{ONO})$ ]. First, it is clear that the part of the macrocycle from $N(3)$ to $N(9)$ through $N(6)$ and including the pyridine ring is very similar to that observed in the planar structure. The first change in torsion angles between the two structures is apparent at $\mathrm{C}(16)$ as the $\mathrm{C}(16)-\mathrm{N}(3)-\mathrm{C}(4)-\mathrm{C}(5)$ torsion angle is $141^{\circ}$ rather than $164^{\circ}$. This is the only sign of strain in the whole folding operation, as around the $\mathrm{N}(3)-\mathrm{C}(4)$ bond there are two $\mathrm{H}-\mathrm{N}-\mathrm{C}-\mathrm{C}$ torsion angles of $c a$ $24^{\circ}$ and $\mathrm{Ni}-\mathrm{N}(3)-\mathrm{C}(4)-\mathrm{C}(5)$ is $9.5^{\circ}$. From here unstrained angles of $-79(1),-72(1)$ and $74(1)^{\circ}$ around the $\mathrm{N}(3)-\mathrm{C}(16), \mathrm{C}(16)-\mathrm{C}(15)$ and $\mathrm{C}(15)-$ $\mathrm{C}(14)$ bonds, respectively, lead to $\mathrm{N}(13)$ in a position $2 \cdot 11 \AA$ above the $\mathrm{NiN}_{3}$ plane. The geometry of this Ni , $\mathrm{N}(3), \mathrm{N}(13), \mathrm{C}(14), \mathrm{C}(15), \mathrm{C}(16)$ ring is a very flattened chair with $\mathrm{C}(15)$ only $0.17 \AA$ from the $\mathrm{NiN}_{2}$ plane. Torsion angles around the $\mathrm{C}(12)-\mathrm{N}(13)$ and $\mathrm{N}(13)-$ $\mathrm{C}(14)$ bonds are comparable to those in $\left[\mathrm{Ni} L^{2}\right]^{2+}$ at ca $180^{\circ}$. The other six-membered ring containing Ni , $\mathrm{N}(13), \mathrm{N}(9)$ is much less strained as $\mathrm{C}(11)$ is $0.74 \AA$ from the $\mathrm{NiN}_{2}$ plane. It is noticeable that the $\mathrm{C}(7)-\mathrm{C}(8)-\mathrm{N}(9)-\mathrm{C}(10)$ torsion angle is $-161(1)^{\circ}$, much closer to $180^{\circ}$ than the analogous angle about $\mathrm{N}(3)-\mathrm{C}(4)$, again emphasizing that this side of the macrocycle is more strain-free.

Despite these variations in the torsion angles described above, the overall conformation of the macrocycle approximates to $C_{s}$ symmetry, as indeed it does in $\left[\mathrm{Ni} L^{2}\right]^{2+}$. This is shown clearly by the torsion

Table 3. Torsion angles $\left({ }^{\circ}\right)$

angles in Table 3. The variations from $C_{s}$ symmetry are also illustrated by planes 1 and 5.* From plane 5, the pyridine ring plane, we note that $\mathrm{N}(3)$ is 0.22 and $\mathrm{N}(9)$ $0.62 \AA$ above the plane. The two methyl groups C(17) and $C(21)$ are also on this (positive) side of the plane. $N(13)$ is -1.42 (1) $\AA$ from the plane, however, indicating that the macrocycle folds such that $N(13)$ approaches the two H atoms on $\mathrm{C}(4)$ and $\mathrm{C}(8)$ and avoids the two methyl groups. Karn \& Busch (1969) were not able to prepare racemic $\left[\mathrm{Ni} L^{2}(\mathrm{en})\right]^{2+}$, the $\alpha$ form in which one of the methyl groups would have to be the same side as $\mathrm{N}(13)$, and from models they concluded that the racemic form of the macrocycle could not fold without one of the methyl groups becoming too close to other atoms in the macrocycle. While models can be misleading, support for this view comes from the present structure where close contacts exist between $H(4)$ and $H(8)$ and several atoms [e.g. $\mathrm{H}(4) \cdots \mathrm{C}(15) 2 \cdot 66, \mathrm{H}(8) \cdots \mathrm{C}(11) 2 \cdot 65 \AA$ ] and clearly if (as in the racemic form) $\mathrm{H}(4)$ or $\mathrm{H}(8)$ were replaced by a methyl group the distances would be too short. Thus, it seems likely that Karn \& Busch (1969) are correct in their view.

The Ni atom is $0.52 \AA$ from the pyridine ring plane although it is coplanar with $N(3), N(6)$ and $N(9)$ (see plane 1).* Indeed, the angle between the pyridine ring and the $\mathrm{NiN}_{3}$ plane is $16 \cdot 1^{\circ}$ and it can be presumed that this angle is distorted from $0^{\circ}$ by the steric effects of the fold in the macrocycle. Thus, the fold leads to a larger 'hole' and subsequently to longer $\mathrm{Ni}-\mathrm{N}$ bond lengths than in $\left[\mathrm{Ni} L^{2}\left(\mathrm{NO}_{2}\right)(\mathrm{ONO})\right]$ where the macrocycle is planar. An additional (but not independent) reason for the lengthening (about $0.07 \AA$ in all four bonds) could involve the en ligand. For, if the Ni atom

[^2]were more strongly bonded to the macrocycle, then contacts between the en ligand and the macrocycle $L^{2}$ would be decreased. As it is, there are several $\mathrm{H} \cdots \mathrm{H}$ contacts between the two ligands of $c a 2 \cdot 2 \AA$. The $\mathrm{Ni}-\mathrm{N}(\mathrm{en})$ bond lengths are $\mathrm{Ni}-\mathrm{N}(1) 2 \cdot 162$ (13), $\mathrm{Ni}-\mathrm{N}(2) 2.096(14) \AA ; \mathrm{N}(1)$ is trans to $\mathrm{N}(13)$ and it may be that the $\mathrm{Ni}-\mathrm{N}(1)$ bond length is thus more susceptible to repulsions from the macrocycle atoms than is $\mathrm{Ni}-\mathrm{N}(2)$.

There are no strong contacts between the cations and anions. The shortest distance from a non-hydrogen atom in the cation to a perchlorate oxygen is $3.02 \AA$ from $N(1)$ to $O\left(13^{v}\right)$. There are several contacts of this length which may indicate weak hydrogen bonds of the type $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$, but clearly, in view of the disorder among the perchlorate anions, these interactions must be very weak.

We thank A. W. Johans for his assistance with the crystallographic investigations.
