

Fig. 1. A view of the molecule showing the atom numbering and torsion angles ( ${ }^{\circ}$ ) for the ring bonds. Torsion angles have an e.s.d. of $0 \cdot 2^{\circ}$. The sign convention is that of Klyne \& Prelog (1960).
$\left(\mathrm{SiMe}_{2} . \mathrm{NSiMe}_{3}\right)_{3}$, which has bulky substituents, is also non-planar (Adamson \& Daly, 1970).

The $\mathrm{Si}-\mathrm{N}$ lengths cover a wide range $[1.698$ (3) to 1.776 (3) $\AA]$. The shortest are those involving $\mathrm{Si}(7)$, which is bonded to an electronegative $F$ atom, and those which are exocyclic to the four-membered ring. This shortening of $\mathrm{Si}-\mathrm{N}$ bonds exocyclic to $\mathrm{Si}_{2} \mathrm{~N}_{2}$ rings appears to be general (Wheatley, 1962; Clegg,

Klingebiel, Krampe \& Sheldrick, 1980; Clegg, Klingebiel \& Sheldrick, 1980).

All N atoms have essentially planar coordination, as is usual in such compounds (Bürger, 1973).

I thank $\operatorname{Dr}$ U. Klingebiel for providing crystals and the Verband der Chemischen Industrie for financial support. All computer programs were written by WC and Professor G. M. Sheldrick.

# The Structure of Benzoin 

By Masao Haisa, Setsuo Kashino and Michihiro Morimoto<br>Department of Chemistry, Faculty of Science, Okayama University, Tsushima, Okayama 700, Japan

(Received 16 May 1980; accepted 8 July 1980)

Abstract. $\mathrm{C}_{14} \mathrm{H}_{12} \mathrm{O}_{2}$, m.p. 409-410 K , monoclinic, $P 2_{1} / a, a=18.76(2), b=5.765$ (5), $c=10.44$ (2) $\AA$, $\beta=107 \cdot 1(2)^{\circ}, D_{m}=1 \cdot 29, D_{x}=1.307 \mathrm{Mg} \mathrm{m}^{-3}, Z=4$. The structure was refined to $R=0.082$ for 1820 non-zero reflexions. Molecules related by a 2, axis are linked together by bifurcated hydrogen bonds to form columns along $b$. The columns are held together by van der Waals interactions along $a$ and $c$. The keto group makes a dihedral angle of $12.0(1)^{\circ}$ with the plane of the phenyl ring attached to it. The dihedral angle between the two terminal phenyl rings is $64.5(1)^{\circ}$. The torsion angle $\mathrm{O}=\mathrm{C}-\mathrm{C}-\mathrm{O}$ is $26.0(4)^{\circ}$. The $\mathrm{O} \cdots \mathrm{O}$ distance is 2.585 (4) $\AA$, but there is no intramolecular hydrogen bond between the O atoms.

Introduction. The present work forms part of a study on the relationship between molecular conformation and crystal structure for aromatic compounds in which two benzene rings are separated by two bonding atoms. It has been shown previously that when the two bonding atoms are different the two benzene rings usually make a dihedral angle of about $60^{\circ}$ (Kashino, Ito \& Haisa, 1979). The molecular conformation of benzoin is of particular interest because of its ability to form intramolecular hydrogen bonds in solution (Joris \& Schleyer, 1968), and its use as a chelating agent (Koester \& Rotermund, 1965). The unit-cell dimensions have been obtained (Prasad \& Shanker, 1936), but the crystal structure has not been determined.

Crystals obtained from an ethanol solution were prisms elongated along $b$ and bounded by $\{100\},\{001\}$ and $\{201\}$. Intensity data were collected on Weissenberg photographs with crystals $0.4 \times 2.1 \times 0.3 \mathrm{~mm}$ for the layers $h 0 /$ to $h 4 l$, and $0.5 \times 0.5 \times 0.4 \mathrm{~mm}$ for the layers $h k 0$ to $h k 8$. Visually estimated intensities were corrected for Lorentz and polarization factors and for spot shape, but no absorption correction was made $\mid \mu\left(\mathrm{Cu} K(x)=0.70 \mathrm{~mm}^{-1} \mid\right.$. Intensities of 1820 non-zero

reflexions ( $74 \%$ of the reflexions within the $\mathrm{Cu} \mathrm{Kı}$ sphere) were placed on an approximately absolute scale by Wilson's plot ( $B=3 \cdot 5 \AA^{2}$ ).

The structure was solved by a symbolic-addition procedure. The H atoms were located from a difference Fourier map. The refinements were made by blockdiagonal least-squares calculations. The weighting scheme during the later stages was: $w=1.0$ for $0<$ $\left|F_{0}\right| \leq 8 \cdot 0, w=\left(8 \cdot 0 /\left|F_{0}\right|\right)^{2}$ for $\left|F_{0}\right|>8 \cdot 0$. The final $R$ was 0.082 for the non-zero reflexions. Atomic scattering factors were taken from International Tables for $X$-ray Crystallography (1974). Computations were carried out at the Okayama University Computer Center. The programs used were SIGM. TANG, HBLS-5 and DAPH (Ashida, 1973), and MOLCON (Fujii, 1979).

The final atomic parameters are listed in Table 1.* A projection of the crystal structure viewed along $b$ is

[^0]Table 3. Least-squares planes and displacements ( $\AA$ ) of atoms

shown in Fig. 1. Bond lengths and angles are given in Table 2, and the displacements of atoms from the least-squares planes in Table 3.

Discussion. In the crystals molecules related by a $2_{1}$ axis are linked together by bifurcated hydrogen bonds $\mathrm{O}\left(2^{\mathrm{i}}\right) \cdots \mathrm{O}\left(1^{\mathrm{ii}}\right) 2 \cdot 842(4), \mathrm{H}\left(11^{\mathrm{i}}\right) \cdots \mathrm{O}\left(\mathrm{l}^{\mathrm{ii}}\right) 2 \cdot 10(4) \AA$, $\mathrm{O}\left(2^{\mathrm{i}}\right)-\mathrm{H}\left(11^{\mathrm{i}}\right) \cdots \mathrm{O}\left(1^{\mathrm{ii}}\right) \quad 136(3), \quad \mathrm{H}\left(11^{\mathrm{i}}\right) \cdots \mathrm{O}\left(1^{\mathrm{ii}}\right)-$ $\mathrm{C}\left(13^{\mathrm{ii}}\right) 119(1)^{\mathrm{o}} ; \mathrm{O}\left(2^{\mathrm{i}}\right) \cdots \mathrm{O}\left(2^{\mathrm{ii}}\right) 3 \cdot 000(4), \mathrm{H}\left(11^{\mathrm{i}}\right) \cdots$ $\mathrm{O}\left(2^{i i}\right) \quad 2 \cdot 17(4) \AA, \quad \mathrm{O}\left(2^{i}\right)-\mathrm{H}\left(11^{i}\right) \cdots \mathrm{O}\left(2^{i i}\right) \quad 148(3)$, $\mathrm{H}\left(11^{\mathrm{i}}\right) \cdots \mathrm{O}\left(2^{\mathrm{ii}}\right)-\mathrm{C}\left(14^{\mathrm{ii}}\right) 113(1)^{\circ} \mathrm{l}$ to form columns along $b$. The columns are held together along $a$ and $c$ by van der Waals interactions between molecules (i) and (iii), and (i) and (iv). The energies are estimated to be -21.4 and $-17.2 \mathrm{~kJ} \mathrm{~mol}^{\text {' }}$, respectively, from the universal potential of Kitaigorodsky (1973), in agreement with the morphology of the crystals. The phenyl ring ( $A^{i}$ ) attached to the carbonyl group overlaps with ( $\left.A^{\mathrm{iii}}\right)$ related to it by 1 . The interplanar distance is $3.51 \AA$, short contacts being $C\left(3^{i}\right) \cdots C\left(13^{\text {iii }}\right) 3.506$ (4) and $\mathrm{C}\left(1^{\mathrm{i}}\right) \cdots \mathrm{C}\left(2^{\mathrm{iii}}\right) 3 \cdot 535$ (4) $\AA$. The dihedral angle of $85 \cdot 3(1)^{\circ}$ between the rings $\left(A^{\mathrm{i}}\right)$ and $\left(B^{\mathrm{iv}}\right)$ is close to that found in benzene. The angle between rings $\left(B^{i}\right)$ and $\left(B^{i \cdot}\right)$ is $51 \cdot 1(1)^{\circ}$. The cooperative interaction of the hydrogen bonding around the 2, axis with the overlapping of the phenyl rings $(A)$ related by $\overline{1}$ results in the $P 2_{1} / a$ structure.

The molecule is composed of three planes: the keto group and phenyl groups $(A)$ and $(B)$, Table 3. The torsion angle $\tau_{1} \quad[\mathrm{C}(2)-\mathrm{C}(1)-\mathrm{C}(13)-\mathrm{O}(1)]$ is $-12 \cdot 5(4)^{\circ}$, which favours conjugation. The angle $\tau_{2}$
$[\mathrm{O}(1)-\mathrm{C}(13)-\mathrm{C}(14)-\mathrm{O}(2)], 26 \cdot 0(4)^{\circ}$, and thus $\tau_{3}$ $|C(1)-C(13)-C(14)-C(7)|, \quad 84.9(3)^{\circ}, \quad$ are determined by the intermolecular hydrogen bonding. This small $\tau_{2}$ results in a short $O(1) \cdots O(2)$ distance, 2.585 (3) $\AA$, but there is no intramolecular hydrogen bond between the O atoms. The conformation corresponding to $\tau_{3}$ is trans in related compounds which have no intermolecular hydrogen bonding: $\tau_{3}=175.4^{\circ}$ for deoxyanisoin (Norment \& Karle, 1962) and $179.9^{\circ}$ for phenyl benzoate (Adams \& Morsi, 1976). The conformation around the $\mathrm{C}(14)-\mathrm{C}(7)$ bond corresponds to gauche, $\tau_{4}|C(13)-C(14)-C(7)-C(8)|$ being $68.9(3)^{\circ}$, and $\tau_{5}[\mathrm{O}(2)-\mathrm{C}(14)-\mathrm{C}(7)-\mathrm{C}(8)]$ $-48 \cdot 1(4)^{\circ}$. The conformations around the exocyclic bonds described above result in a dihedral angle of $64.5(1)^{\circ}$ between the two phenyl rings $(A)$ and $(B)$. A calculation made by assuming the universal potential of Kitaigorodsky (1973) shows that the energy of the intramolecular van der Waals interactions between the two rings takes a minimum value of $-4.2 \mathrm{~kJ} \mathrm{~mol}^{-1}$ at the observed conformation. The relationship between the carbonyl $\mathrm{C}=\mathrm{O}$ length and the $s$ character of the C atom found for ketones (Kashino \& Haisa, 1977) also holds for benzoin.
