#### Abstract

Pd}\left(\mathrm{C}_{12} \mathrm{H}_{8} \mathrm{~N}_{2}\right)_{2}\right]\left(\mathrm{ClO}_{4}\right)_{2}, \quad \mathrm{C}_{24} \mathrm{H}_{16} \mathrm{~N}_{4} \mathrm{Pd}^{2+}\).$2 \mathrm{ClO}_{4}^{-}$, monoclinic, $I 2 / c, a=14.557$ (6), $b=$ 10.982 (5), $c=14.880$ (6) $\AA, \beta=95.51$ (4) ${ }^{\circ}, Z=4$, $U=2368 \AA^{3}, D_{c}=1.87 \mathrm{Mg} \mathrm{m}^{-3}, \mu($ Мо $K \alpha)=1.06$ $\mathrm{mm}^{-1} . R=0.045$ for 2289 reflexions $[I>2 \sigma(I)]$ and 209 parameters. The cation has twofold symmetry. Overcrowding of the ligands is relieved by a tetrahedral distortion of $\mathrm{PdN}_{4}$ [the angle between the planes through $\mathrm{PdN}_{2}$ is $18.7(2)^{\circ}$ ] and by small distortions of the ligands. $\mathrm{Pd}-\mathrm{N}$ distances are 2.059 (4) and 2.043 (4) $\AA$.

Introduction. The dimensions of 1,10-phenanthroline (phen) are such that a planar arrangement of two of these groups about a metal atom, with normal $M-\mathrm{N}$ distances, would give an impossibly close approach of H atoms of opposite ligands (McKenzie, 1971, and references therein). The strain can be relieved by bowing the ligands away from each other (Rund, 1968) in a manner similar to that observed in bis $\left(2,2^{\prime}\right.$ dipyridyliminato)palladium(II) (Freeman \& Snow, 1965) or by a tetrahedral distortion of $\mathrm{PdN}_{4}$.

Compounds do exist with a trans arrangement of planar phenanthrolines, e.g. $\left[\operatorname{Srphen}_{2}(\mathrm{OH})_{4}\right]\left(\mathrm{ClO}_{4}\right)_{2}$.2phen and $\left[\mathrm{Baphen}_{2}(\mathrm{OH})_{4}\right]\left(\mathrm{ClO}_{4}\right)_{2}$.2phen (Smith, O'Reilly, Kennard \& White, 1977), but these have very long $M-\mathrm{N}$ bonds, $\mathrm{Sr}-\mathrm{N}=2.793$ (7) and $\mathrm{Ba}-\mathrm{N}=$ 2.956 (7) $\AA$. Rund (1968) suggested that for $\mathrm{H}-\mathrm{H}$ distances of $2.4 \AA$ the $M-\mathrm{N}$ bond should be at least $2.8 \AA$.
$\left[\mathrm{Pd}\left(\mathrm{C}_{12} \mathrm{H}_{8} \mathrm{~N}_{2}\right)_{2}\right]\left(\mathrm{ClO}_{4}\right)_{2}$ was obtained by the method of Livingstone (1951) and recrystallized from water. A crystal [described approximately by the following Miller indices and distances, $d$, in mm from an arbitrary origin: $\overline{10} 00(0.0052) ; 100(0.0112) ; ~ \overline{1} 10(0.0083) ; 110$ (0.0079); $1 \overline{1} 0$ ( 0.0105 ); $101 \overline{1}(0.0145) ; 237$ ( 0.0171 )] was mounted on a Picker FACS-1 computer-controlled four-circle diffractometer. Cell parameters were determined by least squares from the setting angles of 12
reflexions. 6070 reflexions were measured with graphite-monochromated Mo Ka radiation giving 2289 independent reflexions with $I>2 \sigma(I)$.

Since there are four cations in the cell the Pd must be on a special position. The possibilities are (a) $0,0,0$; $(b)$ $0, \frac{1}{2}, 0 ;$ (c) $\frac{4}{4}, \frac{4}{4}, \frac{4}{4} ;(d) \frac{1}{4}, \frac{1}{4} \frac{3}{4} ;$ and (e) $0, y, 4$. Reflexions $h k l$ with $l$ odd are systematically weak, so (c) and (d) can be rejected; furthermore $(b)$ is equivalent to $(a)$. If the cation is on (a) it must have a symmetry centre, if on (e) a twofold axis.

A Patterson function showed $\mathrm{Pd}-\mathrm{Pd}$ and $\mathrm{Cl}-\mathrm{Cl}$ vectors compatible with Pd on $(a)$ or on $(e)$ with $y \simeq 0$; Cl also has $y \simeq 0$. The $\mathrm{Pd}-\mathrm{C}$ vectors indicated two slightly different orientations of the phenanthrolines which could only be explained if Pd was on the twofold axis. A Fourier synthesis based on signs calculated from $\left[\mathrm{Pdphen}_{2}\right]^{2+}$ and Cl gave the positions of the O atoms.

Least-squares refinement with 2289 reflexions [ $I$ > $2 \sigma(I)]$ gave $R=0.045$ for 209 parameters. The H atoms were located from a difference synthesis. No extinction correction was required. Atomic coordinates are listed in Table 1.*

Calculations were carried out with the following programs: data reduction UCFACS (Duesler \& Raymond, 1971); Fourier syntheses ZALKINS (A. Zalkin, Lawrence Radiation Laboratory, University of California); least-squares refinement, LINUS (Coppens \& Hamilton, 1970); distances and angles, ORFFE (Busing, Martin \& Levy, 1964); drawings, ORTEP (Johnson, 1965). Scattering factors were those of Cromer \& Mann (1968) for Pd, Cl, O, N, and C and Stewart, Davidson \& Simpson (1965) for H.

[^0]Table 1. Fractional atomic coordinates ( $\times 10^{5}$ for Pd and $\mathrm{Cl}, \times 10^{4}$ for $\mathrm{O}, \mathrm{N}$, and C , and $\times 10^{3}$ for H )

Isotropic thermal parameters $\left(\AA^{2} \times 10^{-3}\right)$ are calculated from the $U_{i j}{ }^{*}$ for atoms other than H. $\Delta$ is the deviation $\left(\AA \times 10^{-3}\right.$ ) from the plane through the cation. Where parameters are fixed by symmetry the e.s.d.'s are given as daggers.

[^1]Discussion. The $\left[\text { Pdphen }_{2}\right]^{2+}$ ion, Fig. 1, has twofold symmetry, the N atoms being at the corners of a flattened tetrahedron. $\mathrm{H}(1)-\mathrm{H}\left(1^{\prime}\right)$ and $\mathrm{H}(10)-\mathrm{H}\left(10^{\prime}\right)$ are both $2.0(1) \AA$. Bond distances and angles are listed in Table 2. The mean $\mathrm{Pd}-\mathrm{N}$ distance is 2.051 (3) $\AA$ and the $\mathrm{N}(1)-\mathrm{Pd}-\mathrm{N}(2)$ angle is $81.0(2)^{\circ}$, cf. 2.034 (4) $\AA$ and 80.0 (2) ${ }^{\circ}$ in the bipyridyl complex $\left[\mathrm{Pdbpy}_{2}\right]\left(\mathrm{NO}_{3}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ (Chieh, 1972). The phenanthroline group is almost planar. $\mathrm{N}(1)$ and $\mathrm{N}(2)$ are on opposite sides of the plane so that the angle between the planes through the ligands, $22 \cdot 5^{\circ}$, is larger than the angle between $\operatorname{Pd}, \mathrm{N}(1), \mathrm{N}(2)$ and $\mathrm{Pd}, \mathrm{N}\left(1^{\prime}\right), \mathrm{N}\left(2^{\prime}\right), 18.7(2)^{\circ}$. The corresponding values for $\left[\mathrm{Pdbpy}_{2}\right]\left(\mathrm{NO}_{3}\right)_{2} . \mathrm{H}_{2} \mathrm{O}$ are 33.2 and $24.6(4)^{\circ}$, i.e. the complex with the smallest torsion angle has the longest $\mathrm{Pd}-\mathrm{N}$ distance. The angles in [Ptphen ${ }_{2} \mathrm{Cl}_{2} .3 \mathrm{H}_{2} \mathrm{O}$ (Hazell \& Mukhopadhyay, 1980) are 27.1 and $20.9(5)^{\circ}$.

The $\left[M \mathrm{phen}_{2}\right]^{2+}$ ion does not retain $222\left(D_{2}\right)$ symmetry in the crystal. In the three $\left[M \text { phen }_{2}\right]^{2+}$ complexes which have been determined \{the third is $\left[\mathrm{Hgphen}_{2}\right]\left(\mathrm{NO}_{3}\right)_{2}$ (Grdenić, Kamenar \& HergoldBrundić, 1978) \} the symmetry is reduced to $2\left(C_{2}\right)$, although it is a different twofold axis which is retained

Fig. 1. The $\left[\text { Pdphen }_{2}\right]^{2+}$ ion viewed along the line joining $\mathrm{N}\left(1^{\prime}\right)$ to $\mathrm{N}\left(2^{\prime}\right)$. The chemical symbols for the C atoms have been omitted. H atoms have the same number as the C to which they are bonded.

Table 2. Bond lengths ( $\AA$ ), selected intramolecular distances $(\AA)$, and bond angles $\left({ }^{\circ}\right)$

| $\mathrm{C}(6)-\mathrm{C}(7)-\mathrm{C}(8)$ | 124.6 (5) | $\mathrm{O}(1)-\mathrm{Cl}-\mathrm{O}(3)$ | 102.8 (6) |
| $\mathrm{C}(3)-\mathrm{C}(4)-\mathrm{C}(11)$ | 117.7 (6) | $\mathrm{O}(1)-\mathrm{Cl}-\mathrm{O}(4)$ | 112.1 (4) |
| $\mathrm{C}(8)-\mathrm{C}(7)-\mathrm{C}(12)$ | 116.5 (6) | $\mathrm{O}(2)-\mathrm{Cl}-\mathrm{O}(3)$ | 105.4 (6) |
| $\mathrm{C}(6)-\mathrm{C}(7)-\mathrm{C}(12)$ | 118.9 (6) | $\mathrm{O}(2)-\mathrm{Cl}-\mathrm{O}(4)$ | 109.9 (4) |
| $\mathrm{C}(4)-\mathrm{C}(5)-\mathrm{C}(6)$ | 120.9 (6) | $\mathrm{O}(3)-\mathrm{Cl}-\mathrm{O}(4)$ | 108.3 |
| $\mathrm{C}(5)-\mathrm{C}(6)-\mathrm{C}(7)$ | 121.6 (6) |  |  |

in each case. Here $\mathrm{N}(2)-\mathrm{Pd}-\mathrm{N}\left(2^{\prime}\right)=98.8$ (2) is smaller than $\mathrm{N}(1)-\mathrm{Pd}-\mathrm{N}\left(1^{\prime}\right)=101.8(2)^{\circ}$, which would make $\mathrm{N}(2)-\mathrm{N}\left(2^{\prime}\right)$ smaller than $\mathrm{N}(1)-\mathrm{N}\left(1^{\prime}\right)$. As a result $\mathrm{N}(2), \mathrm{C}(10)$ and $\mathrm{C}(9)$ and their associated H
atoms deviate more from the plane through Cromer, D. T. \& Mann, J. B. (1968). Acta Cryst. A 24, $\left[\mathrm{Pdphen}_{2}\right]^{2+}$ than do $\mathrm{N}(1), \mathrm{C}(1)$, and $\mathrm{C}(2)$ (Table 1).
$\mathrm{Cl}-\mathrm{O}$ distances range from 1.356 to $1.417 \AA$. The $O$ atoms are very anisotropic. Correction of bond lengths assuming riding motion (Busing \& Levy, 1964) gives minimum values of $1.410,1.413,1.439$ and $1.425 \AA$, giving a mean value of $1.422(3) \AA$, cf. 1.433 (3) $\AA$ in $\mathrm{KClO}_{4}$ (Johansson \& Lindqvist, 1977).

#### Abstract

C}_{54} \mathrm{H}_{45} \mathrm{AuP}_{3}^{+} . \mathrm{C}_{24} \mathrm{H}_{20} \mathrm{~B}^{-}, \quad\left[\mathrm{Au}\left(\mathrm{C}_{18} \mathrm{H}_{15} \mathrm{P}\right)_{3}\right]\) $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}\right], M_{r}=1241 \cdot 13$, monoclinic, $P 2_{1} / c, a=$ 16.747 (6), $b=20.645$ (8), $c=18.398$ (7) $\AA, \beta=$ 95.06 (2) ${ }^{\circ}, U=6336 \AA^{3}, Z=4, D_{x}=1.301 \mathrm{Mg} \mathrm{m}^{-3}$, $\mu($ Mo K $\alpha)=2.4 \mathrm{~mm}^{-1}$. Final $R=0.054$ for 8753 reflexions. The Au atom shows trigonal planar coordination with $\mathrm{Au}-\mathrm{P} 2.365$ (3), 2.384 (3), 2.403 (3) $\AA$, and $\mathrm{P}-\mathrm{Au}-\mathrm{P} 115 \cdot 2$ (2), $119 \cdot 3$ (2), $125 \cdot 4$ (2) ${ }^{\circ}$.

Introduction. During attempts to recrystallize $L_{4} \mathrm{Au}^{+} . \mathrm{BPh}_{4}^{-}$( $L=\mathrm{PPh}_{3}$ throughout this paper), large colourless crystals were obtained from acetonitrile. The approximate cell volume, determined from preliminary photographs, indicated that one ligand had been lost. In view of the paucity of information on three-coordinate $\mathrm{Au}^{1}$ complexes, a crystal structure determination was undertaken.

Data were collected on a Stoe four-circle diffractometer with a profile-fitting method (Clegg, 1981).

11522 intensities were measured in the range $7<$ $2 \theta<55^{\circ}$ (monochromated Mo K $\alpha$ radiation). After Lp and empirical absorption corrections (crystal size 0.75 $\times 0.35 \times 0.2 \mathrm{~mm}$ ), averaging equivalent reflexions gave 8753 unique data with $F>4 \sigma(F)$.
The structure was solved by the heavy-atom method and refined to $R_{w}=\sum w^{1 / 2} \Delta / \sum w^{1 / 2}\left|F_{o}\right|=0.054=R$. The weighting scheme was $w^{-1}=\sigma^{2}(F)+0.0005 F^{2}$. The Au and P atoms were anisotropic; the phenyl rings were treated as rigid groups with $\mathrm{C}-\mathrm{C} 1 \cdot 395, \mathrm{C}-\mathrm{H}$ $0.96 \AA$ and all angles $120^{\circ}, U(\mathrm{H})=1 \cdot 2 U(\mathrm{C})$. Final atomic coordinates are given in Table 1, bond lengths and angles in Table 2.* A final difference map showed no peaks $>1 \mathrm{e} \AA^{-3}$.
