# Stacking Variants of $\mathbf{M n P}_{\mathbf{4}}$ : Preparation and Structure of 6-MnP $\mathbf{4}_{4}$ 

By R. Rühl and W. Jeitschko<br>Abteilung Chemie der Universität Dortmund, D-4600 Dortmund, Federal Republic of Germany

(Received 1 July 1980; accepted 18 August 1980)

#### Abstract

Two new polymorphs of $\mathrm{MnP}_{4}$ were prepared by reaction of the elemental components in a tin flux or by chemical transport in the presence of iodine. They can be considered as stacking variants $\left(2-\mathrm{MnP}_{4}\right.$ and $6-\mathrm{MnP}_{4}$ ) of a previously reported modification of this composition which is now called $8-\mathrm{MnP}_{4}$. The structure of $6-\mathrm{MnP}_{4}$ was determined from single-crystal counter data. It is triclinic, space group $P \overline{1}$, with $a=$ 16.347 (3), $b=5.847$ (4), $c=5 \cdot 108$ (3) $\AA$, $\alpha=$ 115.66 (2), $\beta=95.15$ (5), $\gamma=89.21$ (3) ${ }^{\circ}$, and $Z=6$. Refinement resulted in a final $R=0.060$ for 1227 structure factors and 63 variable parameters. The near-neighbor environments are very similar to those of $8-\mathrm{MnP}_{4}$ : The P atoms are tetrahedrally coordinated by Mn and P atoms, and the Mn atoms are octahedrally coordinated by P atoms. The $\mathrm{MnP}_{6}$ octahedra are linked via edges thus forming infinite zigzag chains. The Mn atoms with formal oxidation number +2 ( $d^{5}$ system) are displaced from the centers of their octahedra to form pairs with $\mathrm{Mn}-\mathrm{Mn}$ bonding distances of 2.92 and $2.96 \AA$. In agreement with a simple bonding description based on classical two-electron bonds, $6-\mathrm{MnP}_{4}$ is diamagnetic and semiconducting. As is the case for all transition-metal tetraphosphides the P atoms form a two-dimensionally infinite net of condensed, ten-membered rings. A puckered net of pentagons and hexagons formed by transition-metal and $P$ atoms can be considered as the basic building element of the structures of $\mathrm{CrP}_{4}, 2-, 6-, 8-\mathrm{MnP}_{4}$, and $\beta-\mathrm{FeP}_{4}$. The different stacking possibilities of this net are described in a systematic way.

## Introduction

The polyphosphides of the transition metals ( $T$ ) with the highest P content known so far have the composition $T P_{4}$. Although one or other of these had probably been prepared by Biltz (1941) and coworkers, structurally they were not well characterized and their compositions were usually given with a somewhat lower P content. The tensimetric studies of Biltz and co-workers showed that these compounds
were not stable at higher temperatures under normal pressure and therefore it is difficult to prepare them in single phase by direct reaction of the elemental components. The first of these compounds, $\mathrm{CrP}_{4}$, was prepared in a well crystallized form at high pressure ( $15-65 \times 10^{2} \mathrm{MPa}$ ) but could also be obtained at $3 \times$ $10^{2} \mathrm{MPa}$ (Jeitschko \& Donohue, 1972) and, more recently, by the tin-flux technique (Braun, 1976; Braun \& Jeitschko, 1978). A compound with the composition $\mathrm{MnP}_{4}$ was also first prepared at high pressure (Jeitschko \& Donohue, 1975) but was synthesized later at lower pressure (Braun, 1976; Braun \& Jeitschko, 1978; von Schnering, 1976). More recently, the preparations, crystal structures and properties of $\alpha-\mathrm{FeP}_{4}$ (Jeitschko \& Braun, 1978; Grandjean, Gérard, Krieger, Heiden, Braun \& Jeitschko, 1980), $\beta$ - $\mathrm{FeP}_{4}$ (Sugitani, Kinomura, Koizumi \& Kume, 1978), RuP $_{4}$ and $\mathrm{OsP}_{4}$ (Braun \& Jeitschko, 1978), and $\mathrm{ReP}_{4}$ (Jeitschko \& Rühl, 1979) have been described.

In the present paper we report on two new modifications of $\mathrm{MnP}_{4}$ ( $2-\mathrm{MnP}_{4}$ and $6-\mathrm{MnP}_{4}$ ) and on the structure determination of one of these $\left(6-\mathrm{MnP}_{4}\right)$. They can be considered as stacking variants of the earlier reported modification (Jeitschko \& Donohue, 1975) which will be called $8-\mathrm{MnP}_{4}$ here.

## Sample preparation and properties

In the course of this study we have prepared the three modifications of $\mathrm{MnP}_{4}$ under a variety of reaction conditions but the exact thermodynamic stability ranges of each stacking variant are not known. Frequently, two and sometimes all three modifications were obtained in the same preparation. Our best preparation procedures for single-phase products are as follows.
$6-\mathrm{MnP}_{4}$ is obtained best by the tin-flux technique (Jolibois, 1910; Goryunova, Orlov, Sokolova, Shpenkov \& Tsvetkova, 1968; Baghdadi, Finley, Russo, Arnott \& Wold, 1974; Jeitschko \& Braun, 1977). Powders of the elements (all from Merck: ‘rein') with the atomic ratio $\mathrm{Mn}: \mathrm{P}: \mathrm{Sn}=1: 10: 6$ were annealed in evacuated silica tubes for one or two weeks at temperatures between 820 and 920 K . After
(C) 1981 International Union of Crystallography
quenching, the samples were treated with moderately diluted hydrochloric acid (1:1) to dissolve the matrix of tin phosphides. The resulting crystals of $6-\mathrm{MnP}_{4}$ were not visibly attacked by this procedure. They were analyzed by X-ray fluorescence spectroscopy. No elements other than Mn and P were found. The detectability limit for tin was $<0 \cdot 1 \mathrm{wt} \%$.

The previously characterized modification of $\mathrm{MnP}_{4}$ (Jeitschko \& Donohue, 1975; Braun \& Jeitschko, 1978) - now called $8-\mathrm{MnP}_{4}$ - can also be prepared in single phase by the tin-flux technique with the same starting composition and the preparation conditions as described above for $6-\mathrm{MnP}_{4}$ except that the annealing temperatures are higher: 1020 to $1200 \mathrm{~K} .2-\mathrm{MnP}_{4}$ is obtained by this technique with starting composition $\mathrm{Mn}: \mathrm{P}: \mathrm{Sn}=1: 10: 20$ and with annealing for three weeks at 820 K .

With iodine as catalyst and/or transporting agent we have obtained all three modifications. Here the starting compositions were varied between $\mathrm{Mn}: \mathrm{P}=1: 2$ and $1: 4$. About $1 \mathrm{at} . \%$ of iodine was added. The samples were annealed in sealed evacuated silica tubes for 6 to 8 weeks. Usually there was a temperature gradient in the tubes with the hot end at temperatures ranging between 770 and 970 K ; the cool end was between 50 and 100 K lower. Single-phase 2- $\mathrm{MnP}_{4}$ was obtained only at the colder parts of the tubes via a transport reaction. At the hot ends of the tubes mostly $6-\mathrm{MnP}_{4}$ was observed, but $2-\mathrm{MnP}_{4}$ and $8-\mathrm{MnP}_{4}$ were usually also present in smaller amounts.

In addition to the three modifications of $\mathrm{MnP}_{4}$, other manganese phosphides with lower $P$ content were observed in various preparations. Of these, MnP (Rundqvist \& Nawapong, 1965) was identified, but we have also obtained a compound with higher $P$ content, the powder patterns of which appear to be similar to the pattern given by Biltz, Wiechmann \& Meisel (1937) for the composition $\mathrm{MnP}_{3}$.

Similarly to $8-\mathrm{MnP}_{4}$, crystals of 2 - and $6-\mathrm{MnP}_{4}$ are shiny black, stable in air, and not attacked by non-oxidizing acids. Magnetic measurements with the Faraday technique indicate diamagnetism for all three modifications. The electrical conductivities of 2 - and $6-\mathrm{MnP}_{4}$ were determined between 4 and 400 K with a four-probe technique (Grandjean, Gérard, Krieger, Heiden, Braun \& Jeitschko, 1980). They increase with temperature; thus both compounds are semiconducting.

## Cell dimensions and space group

Single crystals of $6-\mathrm{MnP}_{4}$ were examined with Mo $K a$ radiation in Weissenberg and precession cameras. They have triclinic diffraction symmetry. The structure determination resulted in the centrosymmetric space group P1. Lattice constants were refined from Guinier

Table 1. Powder diagram of $6-\mathrm{MnP}_{4}$
The calculated pattern was generated by a computer program (Yvon, Jeitschko \& Parthe, 1977) with data of the refined structure. [Guinier camera, $\mathrm{Cu} K a$ radiation, $Q=10^{4} / d^{2}\left(\AA^{-2}\right)$.]

powder data (Table 1) with $a$-quartz as standard ( $a=$ $4.9130, c=5.4046 \AA$ ): $a=16.347$ (3), $b=5.847$ (4), $c=5.108$ (3) $\AA, a=115.66$ (2), $\beta=95.15$ (5), $\gamma=$ $89.21(3)^{\circ}, V=438 \cdot 1$ (1) $\AA^{3}$. Lattice constants obtained from samples with different preparation conditions were within the error limits given above for the least significant digits in parentheses. This suggests that the compound has only a limited homogeneity range. With $Z=6$ the calculated density is $4.07 \mathrm{Mg} \mathrm{m}^{-3}$.

The single-crystal diffraction patterns of $2-\mathrm{MnP}_{4}$ usually have systematic non-space-group extinctions which indicate twinning. They could be indexed with a triclinic cell. The cell dimensions refined from Guinier data are: $a=5.861(2), b=5.104(1), c=$ 5.836(2) $\AA, \alpha=93.82(1), \beta=107.31$ (2), $\gamma=$ $115 \cdot 81(1)^{\circ}, V=146 \cdot 1$ (1) $\AA^{3}$. These agree well with those obtained independently for this modification by Noläng \& Tergenius (1980). The results of our single-crystal structure determination will be reported shortly (Jeitschko, Rühl, Krieger \& Heiden, 1980).

## Structure determination

The single crystal of $6-\mathrm{MnP}_{4}$ used for the collection of the intensities was taken from a sample prepared with a tin flux with the starting composition $\mathrm{Mn}: \mathrm{P}: \mathrm{Sn}=$ 1:5:6 which was heated within a few hours to 1100 K . After one week at this temperature the sample was cooled slowly to room temperature within a week.

The crystal was mounted in random position on a four-circle diffractometer with graphite-monochromatized Mo $K \alpha$ radiation, a scintillation counter, and a pulse-height discriminator. $\omega$ scans were taken over a scan angle of $1^{\circ}$ with a speed of $0.05^{\circ} \mathrm{s}^{-1}$. Background was counted for 22 s at both ends of each scan.

All reflections within a half-sphere of reciprocal space up to $2 \theta=60^{\circ}$ were measured. After averaging for equivalent reflections, 2445 unique reflections were obtained for the centrosymmetric space group. No absorption correction was made because of the small size of the crystal $(35 \times 35 \times 50 \mu \mathrm{~m}) ; \mu_{\text {Mо } К \alpha}=6.05$ $\mathrm{mm}^{-1}$. This yields a value of $\mu r=0 \cdot 14$ for the average half-diameter of the crystal.
A Patterson function yielded the locations of the Mn atoms, and the positions of the P atoms were deduced from difference syntheses. The structure was refined with a full-matrix least-squares program (Sheldrick, 1976) using scattering factors for neutral atoms (Cromer \& Mann, 1968), corrected for anomalous dispersion (Cromer \& Liberman, 1970). Weights were assigned according to $w=1 /\left[\sigma^{2}\left(F_{o}\right)+k F_{o}^{2}\right]$ where $k$ is a least-squares parameter which refined to $k=0.00038$ in the final cycles. An isotropic extinction correction parameter was refined and applied to the $F_{c}$ values. Because of systematic errors for weak reflections (small $F_{o}$ values were always greater than their corresponding $F_{c}$ values) caused by imperfections of the graphite monochromator ( $\omega$ scans were taken), all reflections with $F_{o}<5 \sigma$ were assigned zero weight in the final cycles. A final $R=0.060$ was obtained for the 1227 structure factors with non-zero weight in a refinement with isotropic thermal parameters and a total of 63 variable parameters. For all 2445 reflections $R=$ $0 \cdot 128$.* A final difference synthesis showed no features less than -1.6 or greater than $+2 \cdot 1 \mathrm{e} \AA^{-3}$. The atom parameters are listed in Table 2, interatomic distances in Table 3.

[^0]Table 2. Atomic parameters of $6-\mathrm{MnP}_{4}$
All atoms are in the general position of space group $P \overline{1}$. Numbers in parentheses are e.s.d.'s in the least significant digits. Positional parameters are multiplied by $10^{4}$.

## Discussion

Near-neighbor environments in $6-\mathrm{MnP}_{4}$ are very similar to those in $8-\mathrm{MnP}_{4}$. The Mn atoms are surrounded by six P atoms in an approximately octahedral arrangement. The P atoms are tetrahedrally coordinated either by two Mn and two P atoms or by one Mn and three P atoms. Bonding $\mathrm{Mn}-\mathrm{P}$ distances vary between 2.212 and $2.368 \AA$; the $\mathrm{P}-\mathrm{P}$ distances cover the range from $2 \cdot 172$ to $2.269 \AA$. The average distances are very similar to those in $8-\mathrm{MnP}_{4}$ (in parentheses): Mn-P 2.275 (2.282), and P-P 2.228 (2.225 $\AA$ ).

Bonding in $6-\mathrm{MnP}_{4}$ can again be rationalized with a simple covalent model where all near-neighbor interactions are considered as classical two-electron bonds. By
counting the electrons of the $\mathrm{Mn}-\mathrm{P}$ bonds as belonging to the P atoms, the Mn atoms obtain the oxidation number +2 ( $d^{5}$ system). All $d$ orbitals of the Mn atoms can be considered as utilized. The $d_{x^{2}-y^{2}}$ and $d_{z^{2}}$ orbitals participate in the $\mathrm{Mn}-\mathrm{P}$ bonding ('octahedral $d^{2} s p^{3}$ hybrid') and the remaining three $\sim t_{2 g}$ orbitals hold the five electrons which are not involved in $\mathrm{Mn}-\mathrm{P}$ bonding. Four of these are non-bonding and localized in the (say) $d_{x y}$ and $d_{x z}$ orbitals while the fifth electron uses the remaining $d_{y z}$ orbital which overlaps with the corresponding orbital of a neighboring Mn atom, thus forming a two-electron $\mathrm{Mn}-\mathrm{Mn}$ bond. This simple rationalization of the bonding situation is supported by the diamagnetism and the semiconductivity of the compound. The bonding $\mathrm{Mn}-\mathrm{Mn}$ interaction is also evident from the distortions of the coordination polyhedra which allow short $\mathrm{Mn}-\mathrm{Mn}$ interactions of 2.923 and $2.963 \AA$ (Fig. 1). The corresponding distance in $8-\mathrm{MnP}_{4}$ is 2.941 (2) $\AA$, and in $2-\mathrm{MnP}_{4}$ 2.936 (2) Å.

In counting the electrons of the $\mathrm{Mn}-\mathrm{P}$ bonds as belonging to the P atoms, the P atoms may be considered as forming a two-dimensionally infinite polymeric P polyanion. It extends parallel to the $x$ and $z$ directions and consists of condensed ten-membered rings (Fig. 2). The other $M \mathrm{P}_{4}$ compounds ( $M=$ metal) also have such ten-membered P rings.* The differences

Fig. 1. Near-neighbor environments of the Mn atoms in $6-\mathrm{MnP}_{4}$.
in the structures arise through different modes of condensation. These differences are reflected in the different ways the $M P_{6}$ octahedra are linked with each other. In $6-\mathrm{MnP}_{4}$ linear arrays of four edge-sharing octahedra are further linked via edges, thus forming infinite zigzag chains. In $8-\mathrm{MnP}_{4}$ linear arrays of four edge-sharing octahedra are connected with each other via corners.

The structure of $6-\mathrm{MnP}_{4}$ may also be viewed as a stacking of identical two-dimensionally infinite nets, although bonding within and between the nets is of equal strength. Such nets (Fig. 3) were first outlined to describe the topology of $\mathrm{CrP}_{4}$ and $8-\mathrm{MnP}_{4}$ and were later also found in $\beta-\mathrm{FeP}_{4}$ and 2- $\mathrm{MnP}_{4}$. The differences in the structures arise through the different ways these identical nets are stacked on top of each other. Although the nets are identical within themselves their interactions with neighboring nets are not. The differences in near-neighbor interactions of adjacent nets can (aside from distortions of coordination

Fig. 2. Comparison of the crystal structures of $6-\mathrm{MnP}_{4}$ and $8-\mathrm{MnP}_{4}$. On the left-hand sides the arrangements of the $\mathrm{MnP}_{6}$ octahedra are shown. The right-hand sides of the drawings show the condensed ten-membered rings of the phosphorus polyanions. The projection directions are chosen such that the $P$ atoms of the puckered rings do not overlap; the projections are not perpendicular to the planes of the phosphorus polyanions.

Fig. 3. Puckered net of pentagons and hexagons which can be considered as the basic building element of several $M P_{4}$ compounds. The cell dimensions $a$ and $b$ of $\mathrm{CrP}_{4}, 8-\mathrm{MnP}_{4}$, and $\beta-\mathrm{FeP}_{4}$ correspond to the centered rectangular mesh. The cell dimensions $a$ and $b$ of $2-\mathrm{MnP}_{4}$ and $6-\mathrm{MnP}_{4}$ correspond to the primitive mesh outlined on the left-hand side of the figure.
polyhedra) all be described if the near neighbors of the $P$ atoms are considered. All $P$ atoms have three neighbors within one net. Their fourth neighbor belongs to an adjacent net and is either a $P$ or a metal atom. In the latter case the P atom has two metal neighbors: one of its own net and one of the adjacent net above and below. These P atoms are marked with a cross in Fig. 4. All possible ways of connecting adjacent nets can be described with the eight orientations of the nets symbolized by the hexagons and the letters $o$ and $p$ augmented by primes and minus signs. With these symbols the five crystal structures known so far to be built up with such nets can be described as follows:

```
2- \(\mathrm{MnP}_{4}: p p, p p, \ldots\)
6- \(\mathrm{MnP}_{4}\) : \(p\) р о \(p^{\prime} p^{\prime} o^{\prime}\), р р о \(p^{\prime} p^{\prime} o^{\prime}, \ldots\)
\(8-\mathrm{MnP}_{4}: p p p p-p-p-p-p, p p p p-p-p-p-p\),
\(\mathrm{CrP}_{4}\) : oo o \(, o o^{\prime}, \ldots\)
\(\beta-\mathrm{FeP}_{4}: 0-0,0-0, \ldots\)
```

It is now clear why we have chosen arabic numbers to differentiate between the three known forms of $\mathrm{MnP}_{4}$ : the numbers indicate how many nets need to be stacked on top of each other to complete one translation period. It is obvious that the stacking

p

$o^{\prime}-12-o^{\prime}$
$\begin{array}{ll}p & -1\end{array}-p$
$-0-120$
$-o^{\prime}-12 o^{\prime}$
$-p^{\prime}-12 p^{\prime}$

Fig. 4. Six-membered rings indicating different orientations of the net of Fig. 3 and its linkages with adjacent nets. A total of eight different possibilities (all with the rings in chair conformations) have to be considered to describe all known stacking variants of such nets: four where the P atoms with two metal neighbors are in ortho (o) positions, and four where these P atoms are in para ( $p$ ) positions. In the lower part of the drawing it is shown how rotations transform certain orientations of the rings into each other. Only three basically different possibilities remain: one with a para form, and two with ortho forms which are related like mirror images.
sequence $p p, p p, \ldots$ might equally well be described with $p^{\prime} p^{\prime}, p^{\prime} p^{\prime}, \ldots$ or with $-p-p,-p-p, \ldots$. Therefore we have indicated in the lower part of Fig. 4 how these symbols are transformed into each other when one structure is looked at from different viewpoints. Thus $6-\mathrm{MnP}_{4}$ can also be described by, for instance, $-p^{\prime}-p^{\prime}-o-p-p-o^{\prime}$, $-p^{\prime}-p^{\prime}-o-p-p-o^{\prime}, \ldots$ if the structure is thought of as being rotated by $180^{\circ}$ around an axis perpendicular to the nets.

It is unfortunate that these stacking symbols do not immediately indicate whether adjacent nets have edge-shared or corner-shared $M P_{6}$ octahedra. However, even when the nets are all approximately parallel to each other, as in $2-\mathrm{MnP}_{4}$, the distortions of the polyhedra allow alternating short and long (bonding and non-bonding) $\mathrm{Mn}-\mathrm{Mn}$ interactions.

It is obvious that further stacking variants are possible. In particular, they should occur in 'solid solutions' of $M \mathrm{P}_{4}$ compositions with more than one kind of metal.

We thank Dipl.-Phys. U. Krieger and Professor C. Heiden for allowing us to quote their results of electrical conductivity measurements. Dr M. Jansen collected the four-circle diffractometer data and Dr G. Meyer (all at Universität Giessen) was responsible for the magnetic measurements. This work was supported by the Fonds der Chemischen Industrie and by a grant from the Deutsche Forschungsgemeinschaft. We would also like to thank the Universität Giessen for a graduation stipend for one of us (RR).
